1. PREFACE

The work of this PhD thesis was performed at the Inflammation Research Unit, Division of Internal Medicine, University Hospital of Zurich. This work is a part of the project number 31-124861 of Swiss National Science Foundation.

The aim of this thesis was to investigate novel mechanisms of inflammation in response to the emerging inflammatory mediators Wnt5A and IL-4 in human vascular endothelial cells.

The data of this study are presented in the form of following manuscripts submitted for publication.

1. Wnt5A/Ryk Signaling Critically Affects Barrier Function in Human Vascular Endothelial Cells

Tom Skaria, Esther Bachli, Gabriele Schoedon

2. IL-4 Causes Hyperpermeability of Vascular Endothelial Cells through Wnt5A Signaling

Tom Skaria, Julia Burgener, Esther Bachli, Gabriele Schoedon

2. ABBREVIATIONS

AJ	Adherens junctions
CAM	Cell adhesion molecules
CAMKII	Calmodulin dependent protein kinase II
CFL	Cofilin
ECIS	Electric cell-substrate impedance sensing
Fzd	Frizzled
GO	Gene ontology
GPCRs	G-protein-coupled receptors
HCAEC	Human coronary artery endothelial cells
HUVEC	Human umbilical vein endothelial cells
IEJ	Inter-endothelial junctions
LIMK	LIM kinase
PCP	Planar cell polarity
ROCK	Rho-associated protein serine/threonine kinase
RTKs	Receptor tyrosine-protein kinases
sFRP	secreted Frizzled related protein
SIR	Systemic inflammatory response
TEER	Trans-endothelial electric resistance
T _H 2 cell	Type 2 helper T cell
TLR	Toll-like receptor
WIF	Wnt inhibitory factor

3. ZUSAMMENFASSUNG

Bei schwerer Sepsis und septischem Schock kommt es zu einer systemischen Entzündungsreaktion (systemic inflammatory response SIR) durch die grosse Anzahl von Zytokinen, welche infolge der Kommunikation zwischen aktivierten Immunzellen und Gefässendothelzellen freigesetzt werden. Die mit der SIR assoziierte Endotheldysfunktion ist der Auslöser für eine schwere Leckage der Gefässe und die Bildung von systemischen Gewebsödemen. Sepsis und Septischer Schock sind noch immer die häufigste Todesursache auf der Intensivstation. Es besteht ein grosser Bedarf an wirksamen Therapien, denn die Blockade der „klassischen Entzündungsmediatoren“ wie TNF- α und IL-1 β konnte das Ueberleben der Patienten nicht verbessern. Andere Therapieversuche waren ebenfalls erfolglos. Vor kurzem entdeckte man hohe Konzentrationen von Wnt5A im Serum und Knochenmark von Patienten mit SIR und septischem Schock. Wnt5A, ein neues Chemokin, wird von menschlichen Makrophagen durch Aktivierung des Toll-like Rezeptors freigesetzt und ist massgeblich beteiligt an der Aufrechterhaltung der Entzündungsantwort dieser Zellen. Wie Wnt5A auf humane Gefässendothelzellen wirkt ist jedoch noch nicht bekannt. Mikrovaskuläre Leckage als Folge gestörter endothelialer Barrierefunktion tritt häufig bei Typ2 T-Helferzell abhängigen allergischen Entzündungsreaktionen auf. IL-4, ein aus Typ2 T-Helferzellen stammendes Zytokin mit inflammatorischen Eigenschaften, beeinträchtigt die Funktion der endothelialen Barriere. Allerdings ist auch über den effektiven Mechanismus der IL-4 abhängigen Endotheldysfunktion wenig bekannt.

Ziele der vorliegenden Arbeit sind (1) Die Prozesse und Signalwege zu identifizieren welche durch Wnt5A in humanen Gefässendothelien aus Koronararterien (HCAEC) reguliert werden, (2) Die Effektoren und den Mechanismus zu identifizieren welcher die Barrierefunktion in IL-4 behandelten Gefässendothelzellen beeinträchtigt.

Mittels systembiologischer Vorgehensweise fanden wir, dass Wnt5A in HCAEC überwiegend Gene und Pathways beeinflusst, welche massgeblich beteiligt sind an der Bildung des Aktinzytoskeletts. Wnt5A beeinflusst die Rho-assoziierte Protein- Serin/Threonin- Kinase (ROCK), welche durch Phosphorylierung LIM-Kinase (LIMK)-2 aktiviert und diese wiederum den Aktin-Depolymerisierungsfaktor Cofilin (CFL)-1 deaktiviert. Durch Anfärbung von Aktinfasern in lebenden Zellen zeigte sich, dass Wnt5A-behandelte HCAEC wegen der gestörten Depolymerisierung vermehrt Aktin- Stressfasern bilden. Dies konnte durch WIF-1, den Ryk-Rezeptor spezifischen Wnt-Antagonisten, verhindert werden. Ausserdem wurden durch Wnt5A die zellulären Adhäsionsverbindungen über b-Catenin und VE- Cadherin gestört, was zu Lücken

zwischen den Zellen in HCAEC Monolayers führte. Kontinuierliche Messung des transendothelialen Widerstandes in lebenden Zellen wies auf erhöhte Permeabilität der Wnt5A-behandelten HCAEC Monolayers hin. Knock-down des Ryk-Rezeptors konnte dies verhindern. Diese Daten deuten darauf hin, dass Wnt5A hauptsächlich Prozesse reguliert, die für die Gestaltung des Zytoskeletts in HCAEC verantwortlich sind. Wnt5A, welches während einer systemischen Entzündungsreaktion von aktivierten Immunzellen freigesetzt wird, könnte somit für die Störung der endothelialen Barrierefunktion verantwortlich sein.

Differentielle Genexpressionsanalyse von IL-4 behandelten HCAEC zeigte überraschenderweise, dass Wnt5A eines der am höchsten hochregulierten Gene ist. Die ontologische Gruppierung der Gene in entsprechenden Pathways zeigte, dass die signifikantesten Pathways diejenigen sind, welche Gene enthalten, die für die Zytoskelettstruktur verantwortlich sind. Gene, die diesen Pathways gehäuft zugeordnet wurden, waren wiederum *LIMK-2* und *CFL-1*. Nach Behandlung von HCAEC mit IL-4 waren LIMK-2 und CFL-1 phosphoryliert, ein Hinweis auf vermehrte Bildung von Aktin-Stressfasern. Durch Sichtbarmachung der Aktinfasern in lebenden Zellen konnte die erhöhte Stressfaserbildung in IL-4 behandelten HCAEC bestätigt werden. Die Stressfaser-bildung in IL-4 behandelten HCAEC war in Gegenwart von WIF-1 erheblich geringer. Nicht-invasive elektrophysiologische Aufzeichnung des Widerstandes in HCAEC Monolayers zeigte, dass die Zellpermeabilität durch IL-4 erhöht wird. Durch spezifisches Silencing der Wnt5A-Expression konnte die Barrierefunktion in IL-4 behandelten HCAEC signifikant verbessert werden. IL-6, welches von IL-4 behandelten HCAEC in grossen Mengen gebildet wird, und von dem man bisher annahm, dass es die Gefässpermeabilität beeinflusst, hatte überraschenderweise keinen Effekt. Durch diese Untersuchung konnte Wnt5A als das Molekül identifiziert werden, welches massgeblich an der erhöhten Gefässpermeabilität beteiligt ist, die durch IL-4 verursacht wird.

Die vorliegende Arbeit weist folglich darauf hin, dass der Wnt5A/Ryk/ROCK Signalweg ein neuer Entzündungspathway ist, welcher unabhängig von proinflammatorischen Zytokinen wie TNF- α und IL-1 β die Gefässpermeabilität beeinflusst. Gezielte Angriffspunkte im Wnt5A Signalweg könnten neue therapeutische Möglichkeiten für Patienten mit Sepsis und schweren systemischen Entzündungskrankheiten bieten.

4. SUMMARY

In severe sepsis and septic shock, immune cells and vascular endothelial cells communicate with each other by releasing and responding to an array of pro-inflammatory cytokines and chemokines, thereby provoking a systemic inflammatory response (SIR). SIR associated endothelial dysfunction is the trigger for severe vascular leakage and systemic tissue edema formation. Sepsis/septic shock is still a major cause of death in intensive care. Efficient therapeutic strategies are in demand since blockade of classical inflammatory mediators like TNF- α and IL-1 β failed to improve patient survival. Other therapeutic trials were also not successful so far. Recently, high levels of Wnt5A have been detected in sera and bone marrow of patients with severe systemic inflammation and septic shock. Wnt5A is a novel chemokine secreted by Toll-like receptor-activated human macrophages, and is crucially involved in sustaining their inflammatory response. However, the targets and functional effects of Wnt5A on human vascular endothelial cells remain unclear. Microvascular leakage due to endothelial barrier dysfunction is a prominent feature of type 2 helper T cell (Th2 cell) mediated allergic inflammation. IL-4, a Th2 cell-derived cytokine with proposed inflammatory properties impairs the barrier function of vascular endothelial cells. However, the effector mechanism responsible for IL-4-induced endothelial barrier dysfunction remains poorly defined.

The present study aims to (1) identify the targets and processes regulated by Wnt5A signaling in human coronary artery endothelial cells (HCAEC), (2) identify the effector and the downstream mechanism impairing barrier function in IL-4-activated HCAEC.

By using a systems biology approach, we found that predominant targets of Wnt5A in HCAEC are clusters of genes significantly involved in actin cytoskeleton remodelling. Wnt5A targeted Rho-associated protein serine/threonine kinase (ROCK) to phosphorylate LIM kinase (LIMK)-2 and inactivate the actin depolymerization factor Cofilin (CFL)-1. Live actin staining in Wnt5A-treated HCAEC showed enhanced stress fiber formation in consequence of reduced actin depolymerization that was prevented by Ryk-specific antagonist Wnt inhibitory factor (WIF)-1. Wnt5A disrupted β -catenin and VE-cadherin adherens junctions forming inter-endothelial gaps in HCAEC monolayers. Live recording of trans-endothelial electric resistance revealed increased permeability of Wnt5A-treated HCAEC monolayers that was prevented by knockdown of Ryk. These data indicate that Wnt5A principally regulates the process of cytoskeleton remodelling in HCAEC. Thus Wnt5A released by activated immune cells during systemic inflammatory response might be responsible for endothelial barrier dysfunction.

Differential gene expression profiling in IL-4-treated HCAEC surprisingly identified Wnt5A among the top upregulated genes, and gene ontology pathway clustering revealed that among the top most significant pathways were those containing genes associated with cytoskeleton remodelling. Genes clustered in these pathways were again *LIMK-2* and *CFL-1*. Following IL-4 treatment of HCAEC, LIMK-2 and CFL-1 were phosphorylated, thereby indicating the possibility of actin stress fiber formation. Live imaging of actin proved the enhanced formation of stress fibers in IL-4-treated HCAEC. Stress fiber formation in IL-4-treated HCAEC was notably decreased in the presence of WIF-1. Non-invasive electrophysiologic recording of HCAEC monolayer resistance demonstrated that IL-4 increased the cellular permeability. Specific silencing of Wnt5A expression significantly improved the barrier function of the HCAEC monolayer upon IL-4 treatment. Surprisingly, IL-6 which is generated in large amounts by IL-4-treated endothelial cells and which is supposed to be responsible for IL-4-induced vascular permeability, had no such effect. This study identifies Wnt5A as an effector molecule critically involved in IL-4 mediated vascular hyperpermeability.

In conclusion, the present study reveals Wnt5A/Ryk/ROCK signaling as a novel inflammatory pathway that affects vascular permeability independent of the pro-inflammatory cytokines TNF- α and IL-1 β . Targeting Wnt5A signaling could provide novel therapeutic options for patients with sepsis and severe systemic inflammatory diseases.

5. INTRODUCTION

5.1 Inflammation and sepsis

Inflammation is a pathophysiological process that develops in response to different stimuli such as infections or tissue injury. It involves the coordinated movement of blood leucocytes and plasma components to the site of infection or injury to minimize tissue damage, thereby providing an early protection to the host. Inflammatory responses caused by microbial infections are well characterized and involve the following mechanisms. Firstly, the innate immune receptors such as nucleotide-binding oligomerization-domain protein (NOD)-like receptors and Toll-like receptor (TLR) present on host mast cells and tissue resident macrophages recognize structures on microbial cells. These microbial structures belong to two major classes; the pathogen-associated molecular patterns (PAMPs) and virulence factors. PAMPs are present in all microorganisms while virulence factors are carried by only pathogens. The binding of these microbial structures by TLR and NOD-like receptors activate macrophages and mast cells, resulting in the production of various inflammatory mediators including tissue factor (TF), cytokines, chemokines, proteolytic enzymes, complement components, eicosanoids, platelet activating lipid factors, vasoactive peptides and vasoactive amines [1]. These mediators along with complement components (eg.C5a) function via autocrine and paracrine signaling to further activate tissue resident macrophages, monocytes and endothelial cells. For example, macrophages challenged with bacterial lipopolysaccharide (LPS) secrete pro-inflammatory cytokines including TNF- α and IL-1 β . These pro-inflammatory cytokines paracrinically act on the local endothelial cells and activate them to upregulate the expression of inflammatory mediators like IL-6, IL-8 and MCP-1 [2] and cell adhesion molecules (CAM).

Sepsis/septic shock is defined as a severe systemic inflammatory response (SIR) to an infectious agent. Clinically, severe SIR also occurs without any obvious infection upon heavy trauma, in cancer, and in states of autoimmune inflammation. Prominent symptoms are rapid rise of body temperature accompanied by drop of systemic blood pressure, persistent hypotension despite fluid resuscitation [3], leucocytosis, thrombocytopenia, disseminated coagulation, hypoxemia, tachycardia and tachypnea, oliguria due to renal failure, metabolic acidosis, and finally organ failure and death. Still, septic shock is the major cause of death in intensive care units with mortality rates ranging from 40 to 70% [3]. A major symptom related with SIR is severe vascular leakage causing systemic tissue edema formation. Dysfunction of the vascular endothelium is suggested to be the major reason for vascular leakage during severe systemic inflammation and sepsis. Therapeutic trials targeting the prototypic

inflammatory mediators TNF- α and IL-1 β have not been successful in treating sepsis and septic shock [4]. The effectors and associated molecular mechanisms responsible for endothelial dysfunction and consequent tissue edema formation in sepsis still remain not fully understood.

5.2 Endothelial cells

The vessel wall of arteries and veins is composed of three layers. The innermost layer is called intima which is constantly exposed to the blood flow as well as to cellular and soluble blood components. The vascular endothelial cells are located in this intima where they attach together at intercellular junctions and form a continuous monolayer to line up the blood vessels [5]. Vascular smooth muscle cells form the middle layer called media [6]. The media is separated from the endothelial and the outer adventitia layers by elastic lamina [7]. The adventitia is composed of fibroblasts, small capillaries, lymphatic vessels, nerves, endothelial progenitor cells and immune cells such as macrophages and dendritic cells [7]. The walls of tiny capillaries are composed of endothelial cells surrounded by basal lamina and few pericytes (Figure 1).

The vascular endothelial cells play an important role in maintaining vascular homeostasis. They preserve blood fluidity [8,9], control blood pressure, prevent the adherence of leucocytes [8] and platelets [9] and regulate vascular permeability [8]. Endothelial cells control coagulation through the surface expression of tissue factor pathway inhibitors such as heparin sulphate proteoglycans and thrombomodulin. Moreover, resting endothelial cells retain the von Willebrand factor in their storage granules called Weibel-Palade bodies (WPBs), thus preventing interaction between endothelial membrane and platelets [8].

Endothelial cells control blood pressure by secreting a number of vasodilator and vasoconstrictor mediators that increase and decrease the tone of the neighboring smooth muscle cell layers. Among such endothelium-derived mediators, nitric oxide acts as a vasodilator whereas endothelin type-1 acts as a vasoconstrictor for smooth muscle cells [9].

Under resting conditions, endothelial cells mask leucocyte interaction proteins such as chemokines and CAM like P-selectin by storing them in WPBs. Moreover, the expression of other CAM like VCAM-1, E-selectin and ICAM-1 are suppressed. This prevents the adherence of leucocytes to resting endothelial cells [8].

Figure 1. Composition of the vascular wall. IEL, internal elastic lamina; EEL, external elastic lamina. Figure adapted and modified from reference [7].

Under physiological conditions, endothelial cells tightly control vascular permeability with the aid of ion channels and intercellular junction proteins. The free efflux of liquid, plasma proteins and blood cells to the underlying interstitial space and tissues are restricted. Thus, endothelial cells act as a semipermeable barrier that maintains the selective passage of blood components at a low rate.

Endothelial cells from different parts of the vascular system exhibit different phenotypic characteristics. It means that even endothelial cells from different anatomic sites within the same individual express different receptors and surface antigens and produce different responses to identical stimuli [9].

5.2.1 Structural components of endothelial barrier

The barrier function of endothelial cells depends on the integrity of the structure that comprises of endothelial cell cytoskeleton, intercellular junction complexes, and cell attachments to basement membrane and extracellular matrix [10].

Endothelial cytoskeleton

Endothelial scaffold structures are microtubules, intermediate filaments and actin filaments. Among these, actin filaments represent the most important cytoskeletal structure to regulate endothelial permeability. Actin filaments are polymers of filamentous actin (F-actin) arranged in a linear fashion. Their stability is highly dependent upon the concentration of intracellular globular actin (G-actin). G-actin monomers polymerize to form F-actin filaments when the intracellular concentration of G-actin reaches above the critical concentration of 0.1 μ M. Under physiological conditions, actin filaments are irregularly scattered all over the cell and even located at the cellular periphery as cortical actin. Signaling proteins such as Rho family GTPases (RhoA, Rac1 and Cdc42) modify the arrangement of the actin cytoskeletal network and generate specialized structures such as actin stress fibers or cortical actin [10]. Stress fibers are contractile actomyosin polymers with inverted polarity which are also linked to α -actinin [11]. Actin cytoskeleton rearrangement and stress fiber formation increase endothelial permeability through mechanisms that are still not fully elucidated [10].

Microtubules are tubular polymers composed of dimers of alpha- and beta-tubulin subunits. The microtubule consists of 13 polymeric filaments which are arranged in parallel to form a ring. As microtubules are crosslinked to actin filaments in endothelial cells, they alter endothelial permeability via mechanisms involving actin filaments. Stabilization of microtubules by polymerization inhibits actin stress fiber formation and hyperpermeability in endothelial cells. On the other hand, depolymerization of microtubules increases actin stress fiber formation, possibly through activation of guanine nucleotide exchange factors and Rho family GTPases like RhoA [10]. Intermediate filaments are composed of protein polymers, especially those of vimentin.

Endothelial intercellular junction complexes

The endothelial intercellular junction complexes or inter-endothelial junctions (IEJ, also referred as inter-endothelial adhesions) in microvascular endothelial cells are of mainly two types, the adherens junctions (AJ) and tight junctions (TJ). AJ represent the most common endothelial cell-cell junctions found in microvascular endothelial cells including peripheral microvascular endothelial cells. AJ are impermeable to larger proteins such as albumin and thus act as

barriers to prevent the passage of macromolecules into tissues and organs. AJ are mainly composed of the transmembrane receptor protein VE-cadherin. The extracellular domain of VE-cadherin of one endothelial cell binds to the extracellular domain of another VE-cadherin expressed on the membrane of an adjacent cell. This forms a seal that prevents the passage of molecules through the inter-endothelial space. The intracellular domain of VE-cadherin is connected to the actin cytoskeleton with the help of catenin family of proteins such as α -, β -, γ - and p120-catenins. A proper assembly and maintenance of VE-cadherin-catenin-actin cytoskeleton complex is highly essential for preserving the structural integrity and function of endothelial barriers. In comparison with AJ, there is little expression of tight junction proteins in peripheral microvascular endothelial cells. TJ composed of proteins such as claudins, occludins and junctional adhesion molecule-A are commonly found in the microvascular endothelial cells of specialized tissues such as blood retinal or blood brain barriers [10].

Endothelial focal adhesions

Focal adhesions attach endothelial cells to their basement membrane. Focal adhesions are small regions in the basolateral membrane, composed of transmembrane receptors called integrins. Integrins are normally present as heterodimers of α - and β - subunits. The intracellular domain of integrins is associated with the actin cytoskeleton with the help of linker proteins such as α -actinin, talin, vinculin or paxillin. They are also able to associate with the actin cytoskeleton directly and function independent of linker proteins. The extracellular domain of integrins binds to matrix proteins such as fibronectin, fibrinogen and vitronectin lodged in the laminin and collagen fibers of endothelial basement membrane. Focal adhesions keep the endothelial cells attached to the substratum and preserve endothelial barrier integrity [10]. Focal adhesion disassembly is regulated by RhoA through the activation of its downstream target Rho-associated protein serine/threonine kinase (ROCK). Activation of ROCK leads to the activation of LIM kinase (LIMK) by phosphorylation, which in turn phosphorylates cofilin (CFL). Phosphorylation inactivates CFL and favours the stabilization of filamentous actin contained within the actomyosin bundles [11].

5.3 Endothelial response in severe systemic inflammation and sepsis

The functions of endothelial cells are heavily altered in diseases like severe systemic inflammation and sepsis [9]. These alterations include a change from the anticoagulant phenotype to a procoagulant state, increased production of vasoactive substances, expression of CAM, and the synthesis of inflammatory mediators including chemoattractants. The

endothelium at this stage is said to be activated. The pro-inflammatory cytokines TNF- α and IL-1 secreted by activated leucocytes act as the prototypic mediators of endothelial activation. The binding of these pro-inflammatory cytokines to their corresponding receptors on endothelial cells initiate signaling mechanisms that activate mitogen-kinase kinase kinases (MAPKKKs). Activated MAPKKKs trigger the pathways activating the transcription factors nuclear factor-kappa-light-chain-enhancer of activated B cells κ B (NF- κ B) and activator protein-1 (AP-1). The activated transcription factors turn on the gene expression of CAM and pro-inflammatory proteins (Figure 2). The CAM expressed on activated endothelial cells, E-selectin, ICAM-1 and VCAM-1 promote the recruitment and adhesion of leucocytes to endothelial cells. The pro-inflammatory mediators include cytokines such as IL-6, chemokines such as IL-8 and MCP-1, enzymes such as cyclooxygenase-2 (COX-2) and effector proteins that are responsible for the rearrangements of actin filaments [8]. Cytokines such as IL-6 and chemokines act on leucocytes and facilitate their recruitment to inflamed tissue. COX-2 aids the biosynthesis of prostaglandin- I_2 to raise the blood pressure. Actin filament rearrangements disrupt IEJ [8] and might induce endothelial barrier dysfunction. But the exact mechanisms mediating these rearrangements remain still unidentified.

Figure 2. Phenotypic changes in resting and activated vascular endothelial cells. Left side: vascular endothelial cells forming a tight cell-cell contact under resting conditions. Right side: activated endothelial cells showing upregulated expression of CAM and chemokines followed by disruption of inter-endothelial contacts. IEJ, inter-endothelial junction.

5.3.1 IL-4 signaling

Activation of the vascular endothelium is also associated with cytokines such as IL-4, secreted by type 2 helper T cell (Th2 cell) population. IL-4 is a multifunctional cytokine that has crucial roles in the regulation of homeostasis and pathogenesis of diseases. Although activated Th2 cells represent the major source of IL-4, it is also produced by basophils, eosinophils and mast cells [12]. IL-4 can bind to two different cell surface receptor complexes known as type I IL-4R and type II IL-4R. Type I IL-4R is composed of IL-4R α and γ c chains and mainly found in hematopoietic cells. Type II IL-4R is expressed by both hematopoietic and non-hematopoietic cells and formed of IL-4R α and IL-13R α 1 chains. The subunits of both IL-4 receptor complexes are constitutively associated with members of Janus protein kinases (Jaks) family such as Jak1 (IL-4R α), Jak2 (IL-13R α 1) and Jak3 (γ c chain). Activation of Jaks followed by ligand-receptor interaction causes tyrosyl phosphorylation and dimerization of signal transducer and activator of transcription 6 (STAT6). STAT6 is then transported to the nucleus to activate the expression of IL-4 responsive genes [13].

IL-4 triggers functionally different intracellular signaling mechanisms by binding to alternative receptors [12]. It induces the differentiation of antigen encountered naïve T cells to form mature effector Th2 cells capable of producing IL-4 and a number of other cytokines such as IL-5 and IL-13. It regulates immunoglobulin (Ig) class switching so that human B cells express IgE and IgG4 [14]. IL-4 induces the “alternative activation” of macrophages to form a group of highly specialized cells called M2 macrophages, the latter playing important roles in inflammation, parasite clearance and tissue repair [12]. Through its effects on multiple cell types, IL-4 plays critical roles in allergic inflammation including allergen-induced asthma, anaphylaxis and rhinitis [15], immune response to extracellular parasites, autoimmunity [14], and tumor inflammation and metastasis [12].

In vascular endothelial cells, IL-4 upregulates the expression of IL-6 and MCP-1 [16,17]. It induces endothelial cells to express VCAM-1 [17,18] that facilitates the adhesion of peripheral blood monocytes [19] and T cells to endothelial cells [20]. Further, IL-4 enhances endothelial permeability. Edema formation resulting from vascular leakage is an important symptom in allergy [21] and autoimmune inflammation. However, the effectors responsible for IL-4-induced endothelial barrier dysfunction remain so far unidentified.

5.3.2 Endothelial barrier dysfunction and vascular leakage

Endothelial barrier dysfunction causes increased efflux of plasma through the vessel wall into the neighboring tissues, leading to the formation of protein-rich tissue edema. Small molecules

and activated leucocytes can pass the endothelial monolayer either through transcellular or paracellular routes. Transcellular passage of proteins is supported by caveolae vesicles. Paracellular passage of leukocytes involves the IEJ. The permeability of the IEJ is dependent on the assembly of the adhesion proteins that constitute IEJ.

Inflammatory mediators increase endothelial permeability through the activation of RhoA/ROCK and its downstream target LIMK. When activated by ROCK-mediated phosphorylation, LIMK phosphorylates the actin depolymerization factor CFL-1. Phosphorylation inactivates CFL-1 and prevents its ability to depolymerize actin filaments leading to the formation of contractile actin stress fibers. The contractile force stretches VE-cadherin inward, requiring a VE-cadherin extracellular domain of one cell to detach from the VE-cadherin extracellular domain of a neighboring cell, forming inter-endothelial gaps [22]. The exact mechanisms are, however, still not well defined.

5.4 Wnts and their signaling mechanisms

Wnts constitute a large family of secreted lipid modified signaling proteins [23-25] that are potent regulators of multiple biological processes such as cell proliferation, cell fate decision and differentiation during embryogenesis and adult homeostasis, and immune responses [26,27]. In mammals, there are 19 genes coding for Wnt proteins [28]. Frizzled (Fzd) proteins are generally suggested to function as receptors for Wnts [26,29]. Wnts function through either the β -catenin dependent canonical pathway or the β -catenin independent non-canonical pathway, the latter being also referred as Wnt/planar cell polarity (PCP) pathway [29].

Canonical Wnt signaling

Canonical Wnt signaling is transduced mainly through Fzd receptors. Fzd receptors belong to the family of G-protein-coupled receptors (GPCRs) [29] and consist of a seven-pass transmembrane region and an extracellular cysteine-rich domain (CRD) homologous to the natural Wnt antagonist, secreted Frizzled related protein (sFRP)-1 [30]. A featured event in canonical Wnt signaling is an increase in cytoplasmic levels of β -catenin, followed by its translocation into the nucleus to regulate gene expression [25]. When Wnt ligands are absent, adenomatous polyposis coli (APC), glycogen synthase kinase 3 (GSK3), the scaffolding protein axin 1, casein kinase I (CKI) and others form a destruction complex. This destruction complex phosphorylates free β -catenin which is not bound to cadherin. The phosphorylated β -catenin gets ubiquitinated and is subsequently targeted for degradation by 26S proteasome, thereby maintaining β -catenin at low levels in resting cells [29,31]. Simultaneously, transcriptional

repressors like transducin-like enhancer proteins (TLEs) bind to DNA binding proteins of the T cell factor (TCF) and lymphoid enhancer-binding factor 1 (LEF1) in the nucleus, leading to the repression of Wnt target genes. Following interaction of a Wnt ligand with Fzd receptor-LRP6 co-receptor complexes, the conformation of LRP6 co-receptor is changed leading to phosphorylation of the co-receptor. This in turn activates G proteins as well as dishevelled proteins, thereby enabling the recruitment of axin 1 to the co-receptor to induce disruption of the destruction complex. As a result, β -catenin increases in the cytoplasm which then translocates to nucleus and interacts with TCF or LEF1. This interaction dissociates TLE repressors from TCF and LEF1 and thus activates the transcription of number genes including MYC and axin 2. Axin 2 aids the assembly of more destruction complexes and thus functions as a feedback inhibitor to the signaling [31]. The sequence of events involved in canonical Wnt signaling is shown in Figure 3. Two examples of canonical Wnt ligands which signal through β -catenin are Wnt3A and Wnt8A [31]. In contrast, Wnt5A has been suggested to repress or inhibit β -catenin dependent canonical Wnt signaling.

Figure 3. Canonical Wnt signaling. Interaction of Wnt with receptor releases β -catenin from the degradation complex. Gene transcription is activated following translocation of free β -catenin from cytoplasm to nucleus. Figure adapted and modified from reference [31].

Non-canonical Wnt signaling

Canonical Wnt signaling has been extensively studied while Wnt/PCP signaling still remains poorly understood with different β -catenin independent pathways existing in parallel [28,31]. The non-canonical Wnt signaling pathways involve either Fzd receptors or non-Fzd receptors such as receptor tyrosine kinase-like orphan receptor-2 (Ror2) and Ryk [29]. One branch is the Wnt/ Ca^{2+} pathway and involves an increase in intracellular Ca^{2+} levels through the activation of phospholipase C (PLC). The Ca^{2+} flux in turn activates calmodulin-dependent protein kinase II (CAMKII), protein kinase C (PKC), and the nuclear factor of activated T cells (NFAT) transcription factor [29,31]. This pathway has been reported to be involved in dorsoventral patterning and separation of tissues in embryos and inhibition of Wnt3/ β -catenin signaling. Recently, CAMKII activation was identified as an essential part of inflammatory Wnt5A/Fzd5 signaling in human macrophages [26]. Another branch of Wnt/PCP pathway involves the activation of Rho which through the regulation of ROCK mediate actin remodelling [29] and alter cytoskeleton arrangement [31]. Wnt4, Wnt5A and Wnt11 are generally classified as non-canonical Wnts [31]. Suggested pathways involved in non-canonical Wnt signaling are summarized in Figure 4.

Figure 4. Non-canonical Wnt signaling. Interaction of Wnt with specific receptor leads to activation one of the three downstream pathways involving Rho GTPases, JNK and PLC. The type of cellular processes regulated depends on the downstream pathway involved. Dsh, dishevelled.

Receptor tyrosine-protein kinases

Wnts can function through transmembrane tyrosine kinase family members called Ror2 and Ryk. Ror2 belongs to the family of the Ror family of receptor tyrosine-protein kinases (RTKs) [32]. Ror2 is distinguished as receptor or co-receptor for Wnt5A and can regulate different Wnt5A signaling pathways by acting alone or in combination with Fzd receptors. Ror2 contains an extracellular CRD domain similar to the extracellular Wnt binding domain of Fzd receptors and sFRP [30], and activates intracellular signaling pathways in response to Wnt5A [28,33]. Wnt5A/Ror2 non-canonical signaling has been described to inhibit canonical Wnt signaling and to play important roles in polarized cell migration [29,32], tumor growth, invasion and metastasis [32].

Ryk is a member of the family of atypical RTKs. It is composed of an extracellular Wnt binding domain, a transmembrane domain and an intracellular kinase domain (Figure 5). Its extracellular domain is glycosylated and is homologous to the endogenous Wnt antagonist Wnt inhibitory factor (WIF)-1. The intracellular kinase domain of Ryk, unlike other members of RTK, is atypical because it lacks tyrosine kinase activity [34] due to the presence of mutations in its evolutionarily conserved tyrosine kinase regions [35]. Therefore, the precise mechanisms by which signals are transmitted from the cell surface to the intracellular compartment upon interaction of Ryk with Wnt ligands remain still unknown. It has been suggested that Ryk signaling activates MAPK pathway [36]. Ryk is overexpressed in epithelial ovarian cancer [37,38].

Figure 5. Structure of Ryk receptor. The extracellular domain is composed of a Wnt inhibitory factor (WIF) module containing two cysteine residues (pink) that surround a tetrabasic cleavage site (TBC site), two leucine-rich repeats (green), and many putative N-linked sites for adding carbohydrates (black sticks). The transmembrane region is composed of tandem cysteine residues. The intracellular domain is composed of a juxtamembrane serine- and threonine (S/T)-rich sequence (white), a catalytically inactive PTK-like domain and a PDZ-binding motif at the C-terminal end. Figure adapted and modified from [34].

A previous study demonstrated that Wnt5A/Ryk signaling inhibits the growth of adult rat corticospinal axons [39]. Moreover, Derailed, a member of Ryk family of receptors in *Drosophila* has been described to act as a receptor for Wnt5A in axon guidance [40]. Wnt5A signaling through Ryk causes repulsive axon guidance in mammals [41]. Recently, it has been shown that Wnt5A/Ryk suppresses the growth of mouse callosal axons [42]. Evidences are still scant to define the downstream mechanism of Wnt5A/Ryk signaling and how Wnt5A/Ryk signaling differs between non-differentiated and fully differentiated cells in terms of its targets and biological function. In the present thesis, we could define a Wnt5A/Ryk signaling pathway in human vascular endothelial cells, affecting vascular permeability (see chapter 6.1).

5.5 Role of Wnt5A in inflammation

Human Wnt5A is a 49kDa protein encoded by one of the Wnt family of genes located on chromosome 3 (in the region between 3p14-p21) [43]. Wnt5A regulates a number of cellular processes such as adhesion, differentiation, migration, polarity and proliferation and plays pivotal roles in post-natal cell functions, immune responses and developmental process of different organs. This suggests that Wnt5A regulates multiple signaling pathways depending on the availability of specific receptors [43,44] and other mediators of the signaling pathway [44], cellular conditions [43], and the presence of natural inhibitors like sFRP. Evidence indicating a crucial role for Wnt signaling in immune response was initially obtained from studies using a 'septic fly' model. It was demonstrated that WntD, a member of Wnt family of proteins in *Drosophila*, was induced through Toll/NF- κ B signaling and regulated innate immune responses to infection. This study proved that mortality rates were higher in flies lacking WntD expression in comparison to flies expressing endogenous WntD. It suggested that under septic conditions, flies deficient of WntD would suffer overstimulated immune responses [45]. A consecutive study demonstrated a functional role for Wnt5A signaling in response to bacterial infections. In that study, human mononuclear cells stimulated with mycobacterial species upregulated Wnt5A and Fzd5 through the activation of Toll/NF- κ B signaling. In response to microbial antigenic stimulation, Wnt5A/Fzd5 signaling upregulated the expression of IL-2 and IFN- γ by antigen presenting cells and T cells, respectively [27]. Increased expression of Wnt5A and Fzd5 has been detected in synovial tissues in rheumatoid arthritis [46], and blockade of Wnt5A/Fzd5 signaling prevented the activation of rheumatoid synovial tissues [47]. Moreover, expression of Wnt5A has been detected in the macrophage-rich regions of murine and human atherosclerotic plaques [48].

Recently, inflammatory Wnt5A signaling in human macrophages was found to be critically involved in severe systemic inflammatory response. Wnt5A protein was highly induced and released upon TLR targeting of macrophages, and was found in substantial quantity in sera of patients with severe sepsis. The study further demonstrated that Wnt5A was capable of sustaining the inflammatory response of macrophages through an autocrine Wnt5A/Fzd5/CAMKII signaling pathway [26]. This study indicates a pivotal role for Wnt5A in inflammation and suggests therapeutic approaches targeting Wnt5A beneficial in treating diseases associated with severe systemic inflammation [49]. Wnt5A is released in substantial amounts from activated macrophages and the vascular endothelium plays an important role in systemic inflammation and septic shock. However, the knowledge of paracrine Wnt5A signaling in vascular endothelial cells is still scant. We addressed this issue in the course of this thesis.

Inflammatory Wnt5A signaling in endothelial cells

A previous study showed that human umbilical vein endothelial cells (HUVEC) treated with a cocktail of TNF- α , IL-1 and IL-8 upregulated the expression of Wnt5A mRNA [50]. As endothelial cells from different vascular environments exhibit functional heterogeneity, Wnt5A signaling in adult vascular endothelial cells may differ from the foetal tissue-derived HUVEC. Another study showed that human aortic endothelial cells (HAEC) treated with Wnt5A expressed pro-inflammatory cytokines such as IL-1, IL-6, and IL-8 [51]. However, the specific targets of Wnt5A in adult human vascular endothelial cells and the precise downstream mechanism by which Wnt5A induces endothelial inflammation have remained unclear.

5.6 Outline of the project

The aim of this thesis was to study the response of human vascular endothelial cells to Wnt5A and IL-4 to define novel mechanisms and signaling pathways of these emerging inflammatory mediators. Following specific aims were addressed:

1. Define all genes and biological processes regulated by Wnt5A signaling in primary human vascular endothelial cells using a standardized genome-wide expression profiling approach.
2. Identify the receptor(s) and the downstream signaling pathways specific for Wnt5A in human vascular endothelial cells.
3. Describe the biological functions of Wnt5A signaling in human vascular endothelial cells.
4. Identify the genes and pathways affecting barrier function in IL-4-activated human vascular endothelial cells using a whole genome transcriptome approach and specific endothelial barrier function assays.

Abstract

Objective— Satisfactory therapeutic strategies for septic shock are still missing. Previously we found elevated levels of Wnt5A in patients with severe sepsis and septic shock. Wnt5A is released by activated macrophages but knowledge of its effects in the vascular system remains scant. Here we investigate the response of human coronary artery endothelial cells (HCAEC) to Wnt5A.

Approach and Results—We used a genome-wide differential expression approach to define novel targets regulated by Wnt5A. Gene ontology analysis of expression profiles revealed clusters of genes involved in actin cytoskeleton remodeling as the predominant targets of Wnt5A. Wnt5A targeted Rho-associated protein serine/threonine kinase (ROCK), leading to phosphorylation of LIM kinase-2 (LIMK2) and inactivation of the actin depolymerization factor cofilin-1 (CFL1). Functional experiments recording cytoskeletal rearrangements in living cells showed that Wnt5A enhanced stress fiber formation as a consequence of reduced actin depolymerization. The antagonist Wnt inhibitory factor 1 (WIF1) that specifically interferes with the WIF domain of Ryk receptors prevented actin polymerization. Wnt5A disrupted β -catenin and VE-cadherin adherens junctions forming inter-endothelial gaps. Functional experiments targeting the endothelial monolayer integrity and live recording of trans-endothelial resistance revealed enhanced permeability of Wnt5A-treated HCAEC. Ryk silencing completely prevented Wnt5A-induced endothelial hyperpermeability. Wnt5A decreased wound healing capacity of HCAEC monolayers; this was restored by the ROCK inhibitor Y-27632.

Conclusions—Here we show that Wnt5A acts on the vascular endothelium causing enhanced permeability through Ryk interaction and downstream ROCK/LIMK2/CFL1 signaling. Wnt5A/Ryk signaling might provide novel therapeutic strategies to prevent capillary leakage in systemic inflammation and septic shock.

Non-standard Abbreviations and Acronyms

CFL1	cofilin-1
ECIS	Electric Cell-substrate Impedance Sensing
Fzd	Frizzled
HCAEC	human coronary artery endothelial cells
IL	interleukin
LIMK2	LIM kinase-2
qRT-PCR	quantitative Real Time-PCR
ROCK	Rho-associated protein serine/threonine kinase
sFRP	secreted Frizzled-related peptide
WIF1	Wnt inhibitory factor 1

Sepsis is a systemic inflammatory response of the organism to an infection. The most serious manifestations of the disease are severe sepsis and septic shock with organ dysfunction and profound hypotension. The pathophysiology is highly complex and includes deregulation of the immune response, severe coagulopathy and endothelial dysfunction¹. A small number of randomized clinical trials showed improved survival in septic patients; however three of these have been disproven in larger studies. The latest example has been trials with activated protein C, which lead to withdrawal of the drug from the market². Despite optimized therapies with replacement of organ function using artificial systems, mortality remains high with a rate of 40–70%¹. The clinical manifestations of sepsis have a strong vascular component, predominantly seen as enhanced vascular leakage due to endothelial barrier dysfunction^{3, 4}.

During systemic inflammation, activated immune cells communicate with the vascular endothelium by release of and response to an array of inflammatory mediators⁵. Inflammatory mediators such as tumor necrosis factor and interleukin (IL)-1 were identified as responsible for disturbed endothelial function with increased leukocyte adhesion and transmigration, loss of control of systemic vascular tone, increased pro-coagulant activity and pronounced vascular leakage. Therapeutic trials targeting these inflammatory mediators have not been efficacious in treating human sepsis⁶⁻⁸.

Recently, Wnt5A was identified as a novel chemokine highly induced and released following Toll-like receptor dependent inflammatory activation of human macrophages and was found in substantial quantities in sera of patients with severe sepsis^{9, 10}. Wnt5A is one of the members of the Wnt family of secreted lipid modified signaling proteins. Wnt5A is capable of sustaining the inflammatory phenotype of macrophages through an autocrine mechanism involving Frizzled (Fzd)-5/CaMKII signaling. This pathway is a target for anti-inflammatory interventions in human macrophages^{9, 11}.

In systemic inflammation and sepsis, inflammatory mediators secreted by activated immune cells act paracrinically on endothelial cells^{1, 12, 13}. Therefore, Wnt5A secreted by activated macrophages might act in a similar manner and contribute to endothelial dysfunction. A recent report indicates inflammatory activation of vascular endothelial cells may occur following Wnt5A exposure¹⁴ but the exact mechanism by which Wnt5A contributes to the inflammatory response of vascular endothelial cells still remain unclear. In the present study, we applied a genome-wide transcriptome analysis to define the targets and pathways of paracrine Wnt5A signaling in our established system of primary vascular endothelial cells, human coronary artery endothelial cells (HCAEC)⁵. IL-1 β , a leading inflammatory cytokine in the vascular system^{5, 15}, was used in parallel as a comparison to Wnt5A and a control for integrity and proper biological function of our HCAEC system. Our study revealed that Wnt5A principally regulated genes involved in cytoskeleton rearrangement. This contrasted with IL-

1 β , which predominantly affected pathways and genes associated with an immune response. We found that Wnt5A critically affects endothelial barrier function and cell migration. We identified the receptor Ryk and downstream Rho-associated protein serine/threonine kinase (ROCK)/LIM kinase 2 (LIMK2)/cofilin-1 (CFL1) signaling as the pathway responsible for Wnt5A-induced cytoskeletal changes in HCAEC. Targeting the Wnt5A/Ryk interaction by either knockdown of Ryk expression or using the Ryk specific soluble antagonist Wnt inhibitory factor 1 (WIF1) abolished cytoskeletal changes and endothelial hyperpermeability. Wnt5A/Ryk signaling might provide novel strategies for therapeutic intervention in systemic inflammation and sepsis.

Materials and Methods

Materials and methods are available in the online-only Data Supplement.

Results

Differential gene expression profiling reveals that Wnt5A predominantly affects genes involved in cytoskeleton rearrangements

To define the genes regulated by Wnt5A treatment in HCAEC, we performed competitive two-color differential gene expression profiling. The transcriptome profiles of HCAEC treated with Wnt5A for 8 h were compared with that of untreated cells (cultured in parallel) using human whole genome oligomicroarrays. Transcriptome profiling of IL-1 β treated HCAEC was performed using the same approach. The well-defined cytokine IL-1 β was used to compare its inflammatory properties with the suspected but not elucidated effects of Wnt5A in the HCAEC system. GeneSpring analysis of the Wnt5A transcriptome in HCAEC revealed 9854 genes, of which 3317 genes were upregulated and 6537 genes were downregulated. GeneSpring analyses comparing Wnt5A and IL-1 β transcriptomes showed that 3188 genes were commonly regulated by both treatments (Figure 1A). The presence of common targets for Wnt5A and IL-1 β points to an inflammatory action of Wnt5A in HCAEC.

The list of two hundred genes highly regulated by Wnt5A and IL-1 β is provided in Tables 1 and 2 of the Online Supplement. Complete data sets for Wnt5A and IL-1 β are available in the NCBI GEO data repository with accession number GSE62281.

To identify the biological processes regulated by Wnt5A or IL-1 β in HCAEC, Metacore gene ontology (GO) analyses were conducted. Using this tool, genes regulated at least 2-fold in

their expression were clustered on the basis of their function to generate statistically significant cellular pathways.

Gene ontology cluster analysis of genes regulated by Wnt5A treatment of HCAEC were mainly associated with cytoskeleton remodeling pathways. The “Cytoskeleton remodeling_TGF, WNT and cytoskeletal remodeling” appeared as the most significant pathway for Wnt5A (Figure 1B), but appeared as only 25th out of 50 pathways significant for IL-1 β (not shown). Genes regulated by both Wnt5A and IL-1 β (Table 1), such as MAPK13 and LIMK2, were mainly concerned with actin polymerization and cytoskeleton remodeling. Among the genes specifically regulated by Wnt5A (Table 2), ARPC1B and CFL1 are involved in actin polymerization, CRK is involved in cell motility and several other genes are involved in angiogenesis. The “Cell adhesion_Chemokines and adhesion” pathway was the second most statistically significant pathway for Wnt5A (Figure 1B), but it appeared as only 45th out of 50 pathways significant for IL-1 β (not shown). In this pathway, Wnt5A-regulated genes were mainly associated with the cytoskeleton targets described above. Additionally, FLNA, a gene involved in branching of actin filaments, was downregulated by Wnt5A (Table 2). In contrast to Wnt5A, gene ontology cluster analysis of genes regulated by IL-1 β were mainly associated with immune response pathways. The “Immune response_HMGB1/RAGE signaling pathway” and “Immune response_HSP60 and HSP70/TLR signaling pathway” were the first and second most significant pathways for IL-1 β in HCAEC (Figure 1C) which involved the upregulation of NF κ B (Table 3). IL-1 β significantly upregulated the expression of inflammatory mediators (IL-6, IL-8, CCL2; Online Supplement Table 2) and cell adhesion molecules (ICAM; Table 3) whereas the expression of these genes was not regulated by Wnt5A. This correlates with our qRT-PCR and flow cytometry analyses and thereby confirms that Wnt5A does not regulate the expression of cell adhesion molecules or proinflammatory cytokines in HCAEC (Online Supplement Figures 1, 2).

Wnt5A receptors in HCAEC

We previously described Wnt5A/Fzd5 signaling as an essential pathway maintaining the production of inflammatory mediators IL-1 β , IL-6 and IL-8 in human macrophages⁹. Since HCAEC did not respond to Wnt5A stimulation with the production of these “Classical” inflammatory molecules or adhesion molecules, and Ryk and Ror2 are other receptors known to be involved in Wnt signaling pathways¹⁶, we checked which of these three receptors (Fzd5, Ryk or Ror2) is responsible for Wnt5A signaling in HCAEC. Using qRT-PCR, we measured Fzd5, Ryk and Ror2 mRNAs expressed constitutively and upon Wnt5A or IL-1 β treatment. Wnt5A treatment did not affect the mRNA levels of Fzd5 (Figure 2A) or Ryk (Figure 2B). In HCAEC treated with IL-1 β , Ryk mRNA was increased approximately 2-

fold while no change was observed in the Fzd5 mRNA level (Figure 2A). We then measured Fzd5 and Ryk mRNA transcripts constitutively expressed in HCAEC. As shown in Figure 2C, Ryk mRNA expression is greater than six times the expression level of Fzd5 mRNA, the latter being very low. Ror2 mRNA expression was undetectable (data not shown). Immunofluorescence staining was performed to corroborate this finding and to verify if IL-1 β upregulates Ryk receptor protein in HCAEC. HCAEC constitutively express substantial amounts of Ryk protein and, consistent with regulation at the mRNA level, HCAEC treated with IL-1 β expressed significantly more Ryk protein compared with the non-treated cells (Figure 2D, upper panel). Constitutive Fzd5 protein expression was scant and remained unchanged with IL-1 β treatment (Figure 2D, lower panel).

Wnt5A phosphorylates LIMK2 and CFL1 proteins through ROCK activation

Wnt5A mainly regulated the functional cluster of genes involved in endothelial actin cytoskeleton remodeling including the ROCK downstream targets *LIMK2* and *CFL1*. LIMK2 is a serine/threonine/tyrosine kinase which, when phosphorylated by ROCK activation, phosphorylates the actin depolymerization factor CFL1¹⁷⁻¹⁹. As Wnt/Planar Cell Polarity signaling involves the activation of ROCK²⁰ and Wnt5A regulated *LIMK2* and *CFL1*, we next checked if LIMK2 and CFL1 proteins are phosphorylated upon treatment with Wnt5A. HCAEC were treated with Wnt5A and the phosphorylated forms of both endogenous LIMK2 and CFL1 were detected by immunofluorescence staining using specific antibodies to phosphorylated LIMK2 and CFL1. Amounts of fluorescent phosphorylated LIMK2 and CFL1 in cells were further quantified using Fiji software. Compared with non-treated cells, a substantial increase in phosphorylated LIMK2 and CFL1 was observed in HCAEC treated with Wnt5A for 1 h and 4 h, respectively (Figure 3A–C).

As LIMK2 and CFL1 are phosphorylated by the activation of ROCK^{17, 19}, we next checked if inhibiting ROCK prevents their phosphorylation upon treatment with Wnt5A. Wnt5A-induced phosphorylation of both LIMK2 and CFL1 was notably suppressed when HCAEC were treated with a combination of Wnt5A and the ROCK-inhibitor Y-27632 (iROCK, Figure 3A–C).

Functional experiments in living cells reveal actin stress fiber formation upon Wnt5A treatment

Since ROCK-mediated LIMK2 and CFL1 phosphorylation causes increased actin fiber bundling and stress fiber formation^{18, 19, 21}, and Wnt5A induced phosphorylation of LIMK2 and CFL1, we next checked if Wnt5A causes actin stress fiber formation. Changes in actin arrangement and F-actin stress fiber formation were recorded in actin-RFP transduced cells. In non-treated HCAEC, an accumulation of non-fibrous g-actin in the perinuclear region was

obvious with few thin actin filaments present. In contrast to this, live actin-RFP showed significantly increased stress fiber formation in Wnt5A treated HCAEC. Similar changes were observed in cells treated with IL-1 β (Figure 4A).

We then checked if Wnt5A-induced stress fiber formation can be prevented by the Wnt antagonists secreted Frizzled-related peptide (sFRP) 1 and WIF1. sFRP1, a member of sFRP family, contains a cysteine-rich domain homologous to the Wnt binding extracellular domain of Fzd and Ror receptors. WIF-Wnt binding domains are homologous to the Wnt binding extracellular domain of Ryk¹⁶. Treatment of HCAEC with Wnt5A in the presence of sFRP1 did not prevent Wnt5A-induced F-actin stress fiber formation, whereas stress fiber formation was notably decreased when HCAEC were treated with a combination of Wnt5A and WIF1 (Figure 4A). This suggests the involvement of Ryk as an upstream receptor for ROCK in Wnt5A triggered cytoskeletal rearrangements in HCAEC. Stress fiber formation induced by IL-1 β remained unaffected by the presence of sFRP1 and WIF1 (Figure 4A).

Wnt5A disrupts adherens junction proteins

As increased stress fiber formation disrupts the assembly of β -catenin and VE-cadherin adhesion proteins in adherens junctions or inter-endothelial junctions²², we next checked if Wnt5A disrupts these adhesion proteins in HCAEC. HCAEC monolayers were treated with Wnt5A for 8 h and the organization of β -catenin and VE-cadherin were examined by immunofluorescence staining. IL-1 β treatment served as a positive control in these experiments. In non-treated cells, β -catenin and VE-cadherin were regularly distributed along the cellular periphery and formed tight contacts at cell borders (Figure 4B). Upon treatment with Wnt5A, β -catenin and VE-cadherin were lost specifically at cell borders resulting in small holes and separations (gaps) between cells. Similar effects were observed in HCAEC treated with IL-1 β (arrowheads, Figure 4B).

Functional experiments targeting the monolayer integrity by live recording of trans-endothelial resistance reveal enhanced permeability through Wnt5A/Ryk signaling

Since Wnt5A disrupted inter-endothelial adherens junctions and induced the formation of intercellular gaps, we proposed that Wnt5A could impair the barrier functions and increase the permeability of an endothelial monolayer. To prove this, HCAEC monolayers cultured in 8W10E+ electrode arrays were treated with Wnt5A and changes in trans-endothelial electrical resistance of the endothelial monolayer were recorded in real time by Electric Cell-substrate Impedance Sensing (ECIS). Upon treatment with Wnt5A, there was a significant decrease in the resistance of HCAEC monolayers to alternating current. The Wnt5A-induced changes in electrical resistivity became significantly evident after 3 h after the addition of

Wnt5A and lasted for more than 10 h. Likewise, treatment with IL-1 β significantly decreased the resistance of HCAEC monolayers (Figure 5A). Our data indicate that inflammatory activation of HCAEC with Wnt5A or IL-1 β affects endothelial barrier function and increases monolayer permeability.

Since HCAEC express constitutively high levels of Ryk, and the Ryk specific Wnt antagonist WIF1 diminished Wnt5A-induced endothelial stress fiber formation, we checked if silencing Ryk expression would prevent Wnt5A induced hyperpermeability of HCAEC monolayers. To silence Ryk expression, HCAEC were transfected with Ryk-specific siRNA. Additionally, HCAEC were transfected with highly validated negative control siRNA to detect off target effects caused by siRNA or transfection reagents. To prove the efficiency of Ryk knockdown, Ryk mRNA expression was compared by qRT-PCR in cells transfected with Ryk-siRNA and in cells transfected with negative control siRNA. Ryk mRNA expression was approximately 70% lower in cells transfected with Ryk-siRNA than in cells transfected with negative control siRNA (Online Supplement Figure 3A). Immunofluorescence staining further confirmed that Ryk-siRNA transfected HCAEC expressed significantly lower amounts of Ryk receptor compared with cells transfected with negative control siRNA (Online Supplement Figures 3B, 3C). These results prove that efficient and specific silencing of Ryk was achieved in HCAEC. Next, Ryk-silenced HCAEC were seeded onto 8W10E+ electrode arrays, treated with Wnt5A or IL-1 β and changes in trans-endothelial electrical resistance were measured in real time by ECIS. Treatment with Wnt5A did not alter the resistance of Ryk-silenced HCAEC. In contrast, IL-1 β significantly decreased the resistance of Ryk-silenced HCAEC (Figure 5B). This result confirms that Wnt5A specifically signals through Ryk in HCAEC.

Wnt5A-impaired motility of endothelial cells is restored by ROCK inhibition

Since Wnt5A induced stress fiber formation and impaired the barrier function of endothelial monolayers, we hypothesized that Wnt5A could also affect the motility of endothelial cells. An ECIS assisted wounding assay was used to investigate whether Wnt5A influences the motility of HCAEC. HCAEC monolayers on single electrode (8W1E) arrays were treated with Wnt5A and subjected to electric current that killed cells in a defined area of the electrode and created a wound of standard size. The migration of viable cells to the wounded area was recorded in real time by ECIS. Treatment with Wnt5A significantly reduced the number of cells migrating to the wounded area (indicated by a significant decrease in impedance) resulting in delayed wound closure. A similar effect was observed in HCAEC treated with IL-1 β whereby cell migration and subsequent wound closure were significantly affected (Figure 6A)

We have shown that Wnt5A-induced phosphorylation of LIMK2 and CFL1 could be suppressed by inhibiting ROCK. ROCK is involved in a variety of cellular processes including cell motility, actin cytoskeleton rearrangements and cell adhesion¹⁹. Therefore, we investigated whether inhibiting ROCK prevents Wnt5A-induced impairment of HCAEC motility in an ECIS assisted wounding assay. HCAEC treated with a combination of Wnt5A and the ROCK inhibitor Y-27632 showed significant increase in cell motility and faster wound closure compared with HCAEC treated with Wnt5A in the absence of ROCK inhibitor. Similar effects were observed in HCAEC treated with a combination of IL-1 β and Y-27632 (Figure 6B). This data further indicate that ROCK is involved in Wnt5A/Ryk signaling in HCAEC.

Discussion

Using a genome-wide expression survey, we characterized the targets and determined the biological function of paracrine inflammatory Wnt5A signaling in a tightly controlled system of adult human vascular endothelial cells. Our study reveals that Wnt5A primarily regulates genes involved in actin cytoskeleton rearrangements in endothelial cells. We have identified a novel Wnt5A/Ryk signaling mechanism that targets the ROCK/LIMK2/CFL1 axis to induce cytoskeleton remodeling and barrier dysfunction in vascular endothelial cells. Gene expression profiling of IL-1 β performed in parallel showed that IL-1 β mainly regulates genes and pathways associated with immune responses, thereby confirming previous findings⁵. The response to IL-1 β proves the integrity of biological functions in our HCAEC system. Our previous study revealed that Wnt5A signals through Fzd5 to cause inflammatory activation of human macrophages⁹. In this study, we found that HCAEC constitutively express high levels of Ryk, and only trace amounts of Fzd5 (Figures 2C, 2D), thereby suggesting that Wnt5A could exert its function without upregulating the level of endogenous Ryk receptors. We further found that Wnt5A-induced stress fiber formation can be prevented by WIF1, thereby pointing to the involvement of Ryk as the receptor for Wnt5A-mediated cytoskeleton remodeling in HCAEC (Figure 4A). Additionally, the transcriptome analysis of the current study shows that Wnt5A downregulates the expression of LRP5 (Table 1). Since LRP5 acts as a co-receptor for Fzd5 in β -catenin dependent signaling^{20, 23}, the Wnt/ β -catenin pathway involving Fzd receptors could be repressed by Wnt5A in HCAEC. This is supported by our finding that β -catenin remains sequestered on the plasma membrane of HCAEC after Wnt5A treatment and is not transported to the nucleus (Figure 4B) to signal via the β -catenin pathway. The subsequent functional experiments demonstrate that Wnt5A induced HCAEC barrier impairment can be prevented by silencing Ryk expression, thereby providing direct

evidence that Wnt5A signals through Ryk (Figure 5). Ryk is a member of the family of atypical receptor tyrosine-protein kinases. It comprises an extracellular Wnt binding domain, a PDZ binding motif and an intracellular atypical kinase domain lacking tyrosine kinase activity. Wnt5A/Ryk signaling has been functionally demonstrated in adult rat corticospinal axons²⁴. Moreover, Derailed, a member of the Ryk family of receptors in *Drosophila*, has been described as acting as a receptor for Wnt5A in axon guidance²⁵. Furthermore, abundant expression of the *Ryk* gene was reported in mouse pulmonary capillary endothelial cells.²⁶ Data obtained in the present study indicate that Wnt5A signaling via ROCK activation induces actin cytoskeletal rearrangements and disrupts VE-cadherin-mediated intercellular adhesion. The involvement of Ryk but not other known Wnt receptors such as Fzd or Ror is further evident from the observation that Wnt5A induced actin stress fiber formation was prevented by the Ryk specific antagonist WIF1, while sFRP1 was ineffective (Figure 4A). Previous studies have already established that inactivation of ROCK and RhoA prevents endothelial hyperpermeability^{27, 28}.

Our study reveals that Wnt5A decreases the motility of HCAEC and combining Wnt5A with the ROCK inhibitor Y-27632 restores the migratory capacity of HCAEC (Figure 6). This is in full accordance with the proposed model of Wnt5A/Ryk signaling. The reduction in endothelial cell motility caused by Wnt5A is due to actin cytoskeleton rearrangements and increased stress fiber formation (Figure 4A) induced by ROCK mediated phosphorylation of LIMK2 and CFL proteins (iROCK, Figure 3A–C).

Our study further demonstrates that IL-1 β signaling significantly upregulates Wnt5A expression in HCAEC (Online Supplement Figure 4). Addressing the question of which transcription factors are involved in mediating IL-1 β -induced expression of Wnt5A in endothelial cells, we found that IL-1 β upregulated NF- κ B (Table 3). As IL-1 β induces Wnt5A in HCAEC, it can be inferred that IL-1 β secreted by activated macrophages in systemic inflammation and sepsis paracrinically triggers endogenous Wnt5A signaling in vascular endothelial cells. Our present study further proves that Wnt5A, unlike IL-1 β , does not induce a cytokine storm (*IL-6*, *IL-8*, *CCL2*; Online Supplement Figure 1) or cell adhesion molecules (*ICAM-1*, *VCAM-1*; Online Supplement Figure 2) in endothelial cells as has been reported previously¹⁴. Data from our genome-wide transcriptome analysis and functional studies indicate that Wnt5A/Ryk signaling in HCAEC is independent of the induction of any other inflammatory mediators. The biological integrity of the cells in our system is proven by the typical inflammatory response to IL-1 β (Online Supplement Figures 1, 2).

Wnt5A expression is elevated in sepsis⁹ and our present study finds Wnt5A as a critical mediator of endothelial hyperpermeability. This warrants further studies to determine the correlation of Wnt5A levels with vascular leakage in appropriate septic animal models.

However, current sepsis animal models fail to mimic the human disease for a number of reasons, and most of the highly successful trials in animal models did not improve patient survival when translated to clinical settings^{12, 29}.

In conclusion, the present study shows for the first time that Wnt5A/Ryk signaling impairs the barrier functions and affects the wound healing of a damaged monolayer of human vascular endothelial cells. This suggests that Wnt5A, secreted by activated macrophages during a systemic inflammatory response, could cause capillary leakage and subsequent edema in severe sepsis. Restoring vascular integrity along with reducing edema is an established factor that improves the prognosis of septic shock. Considering the essential role for Rho/ROCK in Wnt5A signaling in adult human vascular endothelial cells, therapeutic approaches targeting the Wnt5A/Ryk/ROCK signaling pathway would probably improve the prognosis of sepsis.

Significance

Vascular leakage in severe systemic inflammation and septic shock is one of the major reasons that multiorgan failure occurs. With still no good treatment option available it can lead to death in these patients. There is limited knowledge concerning the pathophysiology leading to this leakage and so there are no targeted treatment options. Wnt5A/Ryk signaling in human vascular endothelial cells affects the endothelial cytoskeleton, disrupts inter-endothelial junction assembly, affects endothelial migration, and enhances monolayer permeability causing barrier dysfunction. The Wnt5A/Ryk pathway described here might provide potential novel targets for therapeutic interventions in severe systemic inflammatory diseases and septic shock.

Materials and Methods

Cell Culture

HCAEC (Clonetics, Lonza, Switzerland) were propagated in EBM-2 medium (Clonetics, Lonza) supplemented with EGM-2MV Single Quots with 5% FBS (Clonetics, Lonza) as described¹. Cells were cultured under standard conditions (37°C, 5% CO₂, 80% humidity) in a Class 100 HEPA air filtered system (SteriCult, Fisher Scientific, Switzerland). To avoid masked low-level contamination in cultures, culture medium without antibiotics was used throughout the study. In experimental settings, cells from passages three to six were used and serum concentration of the medium was reduced to 2% FBS. HCAEC were treated with recombinant human/mouse Wnt5A (250 ng/mL; CHO-derived Gln38-Lys380, purity >80%, endotoxin level <1.0 EU/μg of protein; Cat. No. 645-WN, R&D systems, USA), recombinant human IL-1β (20 U/mL; purity >98%; PeproTech, USA), recombinant human secreted Frizzled-related peptide (sFRP)1 (10 μg/mL; purity >95%; Cat. No.1384-SF, R&D systems, USA), recombinant human WIF1 (15 μg/mL; purity >97%; Cat. No. 1341-WF-050, R&D systems, USA). For all pipetting steps, Biopure ep Dualfilter T.I.P.S. sterile filter tips (Eppendorf, Germany) were used.

RNA Isolation and Quantitative Real Time-PCR (qRT-PCR) Analyses

RNA isolation and qRT-PCR were performed as described² with the following modifications and primers. RNA was reverse transcribed into cDNA using TaqMan® Kit (Applied Biosystems, USA). qRT-PCR was performed using Fast SYBR® Green Master Mix and a 7500 Fast Real-Time PCR System (Applied Biosystems, USA). Relative quantification analyses were performed with HPRT gene as endogenous control using RQ Study SDS software v1.4 (Applied Biosystems, USA). Sequence specific PCR detection primers used for Wnt5A, IL-6, IL-8, HPRT, MCP-1, ICAM-1, Ryk and Fzd5 are as follows: Wnt5A forward, 5'-AGT TGC CTA CCC TAG C-3'; Wnt5A reverse, 5'-GTG CCT TCG TGC CTA T-3'; IL-6 forward, 5'-CCT GAC CCA ACC ACA AA-3'; IL-6 reverse, 5'-AGT GTC CTA ACG CTC ATA C-3'; IL-8 forward, 5'-AGA CAG CAG AGC ACA CAA GC-3'; IL-8 reverse, 5'-ATG GTT CCT TCC GGT GGT-3'; HPRT forward, 5'-CCA GTC AAC AGG GGA CAT AAA-3'; HPRT reverse, 5'-CAC AAT CAA GAC ATT CTT TCC AGT-3'; MCP-1 forward, 5'-CAG CCA GAT GCA ATC AAT GC-3'; MCP-1 reverse, 5'-GTG GTC CAT GGA ATC CTG AA-3'; ICAM-1 forward, 5'-TTG GAA GCC TCA TCC G-3'; ICAM-1 reverse, 5'-CAA TGT TGC GAG ACC C-3'; Ryk forward, 5'-TGC CCT CTC CAG AGA CTT GT-3'; Ryk reverse, 5'-CAT CTC GAA GGG GTC AAT GT-3'; Fzd5 forward, 5'-CAT CGA CAT GGA ACG C-3'; Fzd5 reverse, 5'-CGT GAT GGA CTT GAC GC-3'. Temperature cycling conditions of the PCR were as

follows; an initial denaturation step (10 min, 95°C) followed by 40 cycles of denaturation (15 sec, 95°C), annealing (30 sec, 55°C), and extension (30 sec, 72°C).

Constitutively expressed mRNA levels of Fzd5 and Ryk in HCAEC were calculated by the $1/\Delta Ct$ method and values were given as arbitrary units.

Microarray Based Differential Gene Expression Profiling

Gene expression profiling by competitive two-color hybridization of cRNA probes onto 4x44K Human Whole Genome Oligonucleotide microarrays (Agilent Technologies) was performed as described³. Briefly, total RNA was isolated using RNeasy Mini Kit (Qiagen, Basel, Switzerland). Total RNA was quantified by Nanodrop spectrophotometry and RNA integrity was confirmed using the Agilent 2100 Bioanalyzer System (Agilent Tech., Basel, Switzerland). Only RNA samples with a RNA integrity number (RIN) >9 were used for microarray experiments. From each sample, 500 ng of total RNA was reverse transcribed and labeled with Cy3- and Cy5-CTP using the two-color Quick Amp Labeling Kit (Agilent Tech., Switzerland), containing internal control probes and spike in's (labeled Spike A mix with Cy-3 and Spike B mix with Cy-5) for control of reaction performance and background normalization of arrays. cRNA fragmentation and hybridization onto the Human GE 4x44K V2 Microarray chips were performed as per the Quick Amp Labeling protocol (Agilent Techno., version 5.7, 2008). To avoid ozone-induced deterioration of cyanine dyes, array chips were washed with stabilization and drying solution (Agilent Tech., Switzerland).

Microarray Data Analyses

Scanning, feature extraction and preprocessing including data normalization of the microarrays were done by Microarray Scanner and Feature Extraction Software 10.7 (Agilent Tech. Inc.) with default settings for Agilent 4x44 K two-color arrays. The preprocessed data was further analyzed using GeneSpring GX 9.0 Software (Agilent Tech. Inc.) with default settings for two-color arrays using fold change cutoff of 1.5. Gene ontology analysis was performed using Metacore GeneGO software (Thomson Reuters, <http://portal.genego.com>). Genes regulated ≥ 2 -fold in their expression and satisfying a *P* value <0.05 were grouped into pathways according to their biological functions and gene ontology classes.

Immunofluorescence Staining

HCAEC were cultured in four-chamber culture slides coated with rat tail collagen type I (diluted 0.01% in sterile pyrogen-free water; BD Biosciences, USA). To stain for the adherens junction proteins β -catenin and VE-cadherin, HCAEC were grown to a confluent monolayer. After treatment with the stimuli indicated, cells were fixed with 4% formalin in PBS (in case of detecting adherens junction proteins) for 20 min or with a mixture of acetone

and methanol (1:1) for 5 min (in case of Fzd5, Ryk and Wnt5A detection). Slides were washed three times with PBS (pH 7.4) at room temperature (RT). Slides were treated with blocking solution containing 10% goat serum and 1% BSA in PBS for 1 h at RT in case of secondary antibodies derived from goat. Rabbit blocking solution (10% rabbit serum and 1% BSA in PBS) was used in case of secondary antibodies derived from rabbit. Slides were again washed with PBS at RT and incubated with primary antibodies diluted in blocking solution at 4°C overnight. The following antibodies were used for immunofluorescence: goat-anti-Wnt5A (1:50; Cat. No. AF645, R&D Systems), rabbit-anti-Ryk (1:500; Product No. Ab5518, Abcam), rabbit-anti-Fzd5 (1:100; Product No. Ab14475, Abcam), rabbit-anti- β -catenin (1:150; Product No. 9562, Cell Signaling Technology), rabbit-anti-VE-cadherin (1:100; Product No. 2158, Cell Signaling Technology), rabbit-anti-phosphorylated LIMK2 (1:300; pT505; Product No. Ab131343, Abcam), rabbit-anti-phosphorylated CFL1 (1:500; pS3; Product No. Ab100836, Abcam). After three washes with PBS at RT, slides were incubated with Alexa 568 labeled goat anti-rabbit or rabbit anti-goat secondary antibodies (1:2000; Molecular Probes, Invitrogen, USA) depending on the first antibody's species. Incubations with secondary antibodies were combined with Alexa Fluor 488 Phalloidin (1:80; Molecular Probes, Invitrogen, USA) for 1 h at RT in the dark. After three washes with PBS at RT, slides were counterstained with 10 μ g/mL diamidino-phenylindole (DAPI; Sigma-Aldrich) and mounted using ProLong Gold Antifade^R (Life Technologies, USA). Images were captured by Axioskope microscope equipped with an Axio-CamMRm digital camera using AxioVision Rel.4.6 software (Carl Zeiss, Feldbach, Switzerland). The intensity of cellular fluorescent signals was quantified from five different positions of the respective fluorescent images using ImageJ based Fiji software (Fiji is Just ImageJ) and corrected for background fluorescence.

Live Cell Imaging of Actin

HCAEC grown in rat tail collagen type I coated optical 96 microwell culture plates (Thermoscientific, USA) were transduced with CellLight Actin-RFP probe (Cat. No. C10583, Life Technologies, USA) as per manufacturer's instructions. Cells were treated with Wnt5A or IL-1 β alone or in combination with either sFRP1 or WIF1 for 8 h. Images of the cultures were captured with an Axio Observer.Z1 inverted microscope equipped with Axio-Cam MRm digital camera using ZEN 2012 software (Carl Zeiss, Feldbach, Switzerland).

Endothelial Barrier Function Assays

The response of endothelial barrier to a particular stimulus can be assessed non-invasively in a fully standardized manner by continuously recording changes in trans-endothelial electric resistance using Electric Cell-substrate Impedance Sensing (ECIS)^{4, 5}. Endothelial barrier function was recorded in real-time using the ECIS Z Theta system (Applied Biophysics) with

associated software v.1.2.126 PC, as described⁶ with the following modifications. 8W10E+ electrode chamber arrays were equilibrated with EBM-2 basal medium (Clonetics, Lonza, USA) for 24 h and coated with rat tail collagen type I (diluted 0.01% in sterile pyrogen-free water; BD Biosciences, USA) for 12 h. Then HCAEC in EGM2MV complete medium (Clonetics, Lonza, USA) were added to the wells with a density of 80,000- 90,000 cells/well and grown up to 24 h to form dense monolayers (Supplemental Figure 5). Treatments were then conducted by replacing the medium with fresh medium without or with stimuli (Wnt5A, IL-1 β). Measurements were conducted at multiple frequencies ranging from 62.6 Hz to 64 kHz. 8W10E+ contains 40 electrodes per each of its eight wells that traced the cells at 40 different locations in each well and averaged the measurements.

ECIS Assisted Cell Migration Assay

Motility/wound healing assays were performed in ECIS single electrode arrays as described⁷ with the following modifications. 8W1E single electrode chambers were equilibrated with EBM-2 basal medium (Clonetics, Lonza, USA) for 24 h and coated with rat tail collagen type I (BD Biosciences, USA) for 12 h. HCAEC in EGM2MV complete medium (Clonetics, Lonza, USA) were added to the wells with a cell a density of 80,000- 90,000 cells/well. To attain confluent HCAEC monolayers, single electrode array chambers were further incubated for up to 24 h. Stimuli were then added as described above for barrier function assays. 3 h after stimulation, wounding was activated with default conditions for 8W1E arrays (1400 μ A, 60000 Hz, for 20 sec). This fully standardized method produces a highly reproducible wound with an exact diameter of 250 μ m surrounded by undamaged living cells in 8W1E chambers. After wounding, impedance was continuously recorded to observe the migration of cells and formation of confluent monolayer within the defined wounded area.

Ryk Silencing

Specific and functionally validated small interfering RNA (siRNA) against human Ryk (Hs-RYK-9, Cat No. SI02223074) was obtained from Qiagen. To control for “off target” effects of siRNAs, validated AllStars negative control siRNA (Qiagen) with no homology to any mammalian gene was used. For knockdown of Ryk expression, transfection complexes formed of Ryk-siRNA (5 nM) and 6 μ L/mL HiPerFect Transfection reagent (Qiagen GmbH, Hilden, Germany) in EBM-2 basal medium were added to 80% confluent cultures of HCAEC in 24-well plates in a total volume of 500 μ L/well. After 24 h of incubation, transfected cells were split using Trypsin EDTA, seeded onto collagen coated 6 well plates, retransfected for a second round as above and incubated until the cells attained 90% confluency. At this stage, cells were either stimulated with Wnt5A or IL-1 β for 8 h and lysed (for qRT-PCR analyses) or trypsinized and transferred into collagen-coated 8W10E+ arrays (for ECIS barrier function

measurements). Alternatively, HCAEC after one round of Ryk-siRNA transfection were harvested by trypsinization and seeded into collagen-coated BD Falcon 4 chamber culture slides (BD Biosciences, USA). There, a second round of Ryk-siRNA transfection was performed as in 24-well plates. After growing to a confluent monolayer, cells were fixed for immunostainings. Stimulations were carried out in complete EGM medium with 2% FBS devoid of transfection complexes.

ROCK Inhibition

To inhibit ROCK activity, Y-27632 (Cat. No. 688000, Calbiochem; Millipore, USA) was used⁸ at an optimal concentration for this system of 10 $\mu\text{mol/L}$. HCAEC were incubated in medium containing Y-27632 (10 $\mu\text{mol/L}$) alone or in combination with either Wnt5A or IL-1 β for 1 h and 4 h.

Flow Cytometry

HCAEC stimulated with Wnt5A, IL-1 β or combination of these two agents for 24 h were trypsinized and resuspended in PBS supplemented with 0.1% BSA (sample buffer) such that cell density did not exceed more than 10^5 cells/tube. Cells were incubated on ice with directly labeled mouse antibodies against human VCAM-1 (CD106, fluorescein isothiocyanate label, BD pharmingen), ICAM-1 (CD54, phycoerythrin labeled, BD pharmingen), E selectins (CD62E, allophycocyanin label, BD pharmingen) and human integrin $\beta 1$ chain (CD29, allophycocyanin label, BD pharmingen) at a final concentration of 2 $\mu\text{g/ml}$. Isotype controls were performed using mouse IgG polyclonal antibodies. After washing twice with FACS buffer, samples were analyzed using FACS Cantoll cell sorting system (BD Biosciences, Allschwil, Switzerland). Cells were gated according to their forward- and side-scatter pattern, at least 10'000 gated events were acquired for analysis. The fluorescence intensity of corresponding samples labeled with the isotype control antibody was used to set the individual threshold of antigen positivity. Data were analyzed using FlowJo 7.2.5 software.

Statistical Analysis

Data were analyzed using GraphPad Prism software version 5.04 (GraphPad Software, San Diego, CA). An unpaired 2-tailed Student's *t*-test was used and differences were considered statistically significant at $P < 0.05$.

SUPPLEMENTAL MATERIAL

SUPPLEMENTAL RESULTS

Effects of Wnt5A on the Expression of Pro-inflammatory Cytokines

To investigate whether Wnt5A regulates the expression of pro-inflammatory cytokines, HCAEC were treated with Wnt5A (250 ng/mL) for 4 h and 8 h and the regulation of IL-6, IL-8 and MCP-1 mRNA levels were analyzed by qRT-PCR. In parallel, HCAEC were treated with IL-1 β for 4 h and 8 h to validate the biological function of the system. Expression of IL-6 was not significantly regulated by 4 h and 8 h Wnt5A treatments (Online Supplement Figure 1A). Similarly, HCAEC treated with Wnt5A for 4 h and 8 h showed no significant difference in the expression of IL-8 compared with non-treated cells (Online Supplement Figure 1B). Upon Wnt5A treatments for 4 h, but not 8 h, the expression of MCP-1 was significantly upregulated in HCAEC (Online Supplement Figure 1C).

Treatment with IL-1 β significantly upregulated the expression of IL-6, IL-8 and MCP-1 in HCAEC. The highest expression of IL-6 was observed 4 h after IL-1 β treatment (Online Supplement Figure 1D), whereas the expression level of induced IL-8 remained unchanged after 4 h and 8 h IL-1 β treatments (Online Supplement Figure 1E). IL-1 β caused more than 10- fold increase in MCP-1 expression, with its highest expression observed following 8 h treatment (Online Supplement Figure 1F).

Wnt5A Does Not Regulate the Expression of Cell Adhesion Molecules

Pro-inflammatory mediators secreted by activated immune cells activate endothelial cells by upregulating cell adhesion molecules. To determine if Wnt5A regulates the expression of cell adhesion molecules in vascular endothelial cells, HCAEC were treated with Wnt5A as described above for 24 h and the expression of VCAM-1, ICAM-1, E selectins and integrin b1 chain were analyzed by flow cytometry. Wnt5A did not regulate or alter the expression of VCAM-1, ICAM-1, E selectins and integrin b1 chain. HCAEC treated with IL-1 β , which served as a positive control, showed significant upregulation of all four adhesion molecules (Online Supplement Figure 2A).

These findings were confirmed by qRT-PCR. ICAM-1 mRNA expression was not changed following 4 h, 8 h and 24 h Wnt5A treatments (Online Supplement Figure 2B) while ICAM-1 mRNA level was significantly upregulated following 4 h and 8 h IL-1 β treatments (Online Supplement Figure 2C).

IL-1 β Induces the Expression of Wnt5A in HCAEC

Pro-inflammatory cytokines secreted by activated immune cells upregulate inflammatory mediators in endothelial cells. To investigate if the pro-inflammatory cytokine IL-1 β induces

the expression of Wnt5A in vascular endothelial cells, HCAEC were treated with IL-1 β (20 U/mL) for 8 h and the expression of Wnt5A mRNA level was measured by qRT-PCR. Treatment with IL-1 β significantly upregulated Wnt5A mRNA level in HCAEC (Online Supplement Figure 4A). Immunofluorescence staining confirmed increased expression of Wnt5A protein in HCAEC upon IL-1 β treatment (Online Supplement Figure 4B).

SUPPLEMENTAL TABLES

Table 1. Detailed list of the 200 genes highest regulated by Wnt5A in HCAEC.

Figure 5

Figure 5. Formation of confluent HCAEC monolayer in 8W10E+ ECIS array. HCAEC seeded into an 8W10E+ array with a density of 80,000- 90,000 cells/well. Soon after cell seeding, resistance measurements (in Ohms) were started and are shown as normalized resistance (subsequent values were divided by initial values). Rise in resistance with respect to time indicates that cells were forming contacts between each other. The steady state (marked by *) indicates the stage at which maximum resistance is reached to form a tight monolayer. Resistance measurements were conducted in duplicate wells which were grouped and averaged to plot as single curve. Error bars of curves represent SD. Figure shown depict the resistance measurements conducted at 4000 Hz. Red and Blue, Untreated.

6.2 IL-4 Causes Hyperpermeability of Vascular Endothelial Cells through Wnt5A Signaling

Abstract

Microvascular leakage due to endothelial barrier dysfunction is a prominent feature of T helper 2 (Th2) cytokine mediated allergic inflammation. Interleukin-4 (IL-4) is a potent Th2 cytokine, known to impair the barrier function of endothelial cells. However, the effectors mediating IL-4 induced cytoskeleton remodeling and consequent endothelial barrier dysfunction remain poorly defined. Here we have used whole genome transcriptome profiling and gene ontology analyses to identify the genes and processes regulated by IL-4 signaling in human coronary artery endothelial cells (HCAEC). The study revealed Wnt5A as an effector that can mediate actin cytoskeleton remodeling in IL-4 activated HCAEC through the regulation of LIM kinase (LIMK) and Cofilin (CFL). Following IL-4 treatment, LIMK and CFL were phosphorylated, thereby indicating the possibility of actin stress fiber formation. Imaging of actin showed the formation of stress fibers in IL-4 treated live HCAEC. Stress fiber formation was notably decreased in the presence of Wnt inhibitory factor 1 (WIF1). Non-invasive impedance measurements demonstrated that IL-4 increased the permeability and impaired the barrier function of HCAEC monolayers. Silencing Wnt5A significantly reduced permeability and improved the barrier function of HCAEC monolayers upon IL-4 treatment. Our study identifies Wnt5A as a novel marker of IL-4 activated vascular endothelium and demonstrates a critical role for Wnt5A in mediating IL-4 induced endothelial barrier dysfunction. Wnt5A could be a potential therapeutic target for reducing microvascular leakage and edema formation in Th2 driven inflammatory diseases.

Introduction

Interleukin-4 (IL-4) is a multifunctional pleiotropic type I cytokine secreted by activated T helper (Th) 2 cells, basophils, eosinophils and mast cells [1,2]. Functionally, IL-4 induces the differentiation of antigen stimulated naïve T cells to a Th2 phenotype [3,4]. It also regulates immunoglobulin (Ig) class switching so that B lymphocytes express IgE [5], and regulates apoptosis, cell proliferation and expression of several genes in different cell types such as fibroblasts, macrophages, endothelial and epithelial cells [1,2]. IL-4 drives the 'alternative activation of macrophages' to produce the M2 phenotype, which is crucially involved in type 2 immunity. Thus, through its effects on multiple cell types and by binding to alternative cell surface receptors [1], IL-4 plays critical roles in allergic inflammation [6], immune response to extracellular parasites including helminths, autoimmunity [2] and tumor inflammation and metastasis [1,7].

Recent evidence suggests a potential role for IL-4 in generating a proinflammatory environment in vascular endothelial cells (VEC) [8]. VEC are essential for maintaining vascular homeostasis in normal physiological conditions [9]. Under pathophysiological conditions, activated blood components, pathogens or inflammatory mediators such as cytokines act upon VEC and heavily alter their functions, conferring on them an inflamed phenotype. These alterations include a change from the anticoagulant phenotype to a procoagulant state, increased production of vasoactive substances, expression of cell adhesion molecules, synthesis of inflammatory mediators including chemoattractants, and endothelial barrier dysfunction causing microvascular leakage. It has been demonstrated that IL-4 upregulates the expression of vascular cell adhesion molecule (VCAM)-1 [10-12], IL-6 [12-14] and monocyte chemoattractant protein (MCP) [12,14] in human umbilical vein endothelial cells (HUVEC). Moreover, stimulation with IL-4 increased the adhesion of peripheral blood monocytes [15] and T cells [16] to HUVEC. IL-4 has been shown to induce cytoskeletal rearrangements in HUVEC and significantly regulate their proliferation [17]. Further, IL-4 acts as a modest mitogen for both macro and microvascular endothelial cells [8,17-19]. IL-4 has proatherogenic effects and induces the apoptosis of endothelial cells causing increased endothelial cell turnover [20]. It has been demonstrated that IL-4 induces hyperpermeability of HUVEC, causing vascular leakage [21], however, effectors responsible for IL-4 induced endothelial hyperpermeability and consequent barrier dysfunction remain unidentified. Moreover, these previous studies addressing the effects of IL-4 on endothelial inflammation used HUVEC as the primary endothelial cell model system. HUVEC that are obtained from the immune naïve foetal tissue shows significant variations in function compared with adult vascular endothelium and hence may be an inappropriate primary cell model of vascular endothelium [22]. The targets and effects of IL-4 signaling in adult VEC, therefore, may vary from HUVEC and have to be elucidated.

In the present study, we used transcriptome profiling to identify the genes regulated by paracrine IL-4 signaling in our established *in vitro* model of adult VEC, cultured human coronary artery endothelial cells (HCAEC) [23]. Here we identify Wnt5A as one of the genes significantly upregulated by IL-4 treatment. We further demonstrate a critical role for IL-4 induced Wnt5A in impairing barrier function of endothelial monolayers. Our findings suggest a prominent role for Wnt5A in causing microvascular leakage associated with IL-4 driven allergic inflammation and other pathophysiological conditions.

Methods

Cell Culture

HCAEC and human pulmonary artery endothelial cells (HPAEC) purchased from Clonetics (Lonza, USA) were cultured in EBM-2 medium (Clonetics, Lonza, USA) supplemented with EGM-2MV Single Quots and 5% FBS (Clonetics, Lonza) as described previously [23]. For experiments, cells at passages three to six were used and the serum in culture medium was decreased to 2% FBS. Macrophages derived from human PBMC were cultured as described [24]. Cells were cultured under standard conditions (37°C, 5% CO₂, 80% humidity) in a Class 100 HEPA air filtered system (SteriCult, Fisher Scientific, Switzerland). Culture medium without antibiotics was used to prevent masked low-level contamination in cell cultures. Treatments were carried out using recombinant human (rh) IL-4 (4 ng/mL; purity >98%; PeproTech, USA), rh IL-6 (20 U/mL; purity >98%; PeproTech, USA), rh soluble Frizzled-related peptide-1 (sFRP1; 10 µg/mL; purity > 95%; R&D systems, USA), rh/mouse Wnt5A (250 ng/mL; CHO-derived Gln38-Lys380, purity >80%, endotoxin level <1.0 EU/µg of protein; R&D systems, USA) and rh Wnt inhibitory factor 1 (WIF1; 15 µg/mL; purity >97%; R&D systems, USA). Sterile biopure ep Dualfilter T.I.P.S. sterile filter tips (Eppendorf, Germany) were used throughout the study.

RNA Isolation and Quantitative Real-Time PCR (qRT-PCR) Analyses

RNA isolation and qRT-PCR using the HPRT gene as endogenous control were performed as described previously [25]. Sequence specific PCR detection primers used for Wnt5A, IL-6 and HPRT are as follows: Wnt5A forward, 5'-AGT TGC CTA CCC TAG C-3'; Wnt5A reverse, 5'-GTG CCT TCG TGC CTA T-3'; IL-6 forward, 5'-CCT GAC CCA ACC ACA AA-3'; IL-6 reverse, 5'-AGT GTC CTA ACG CTC ATA C-3'; HPRT forward, 5'-CCA GTC AAC AGG GGA CAT AAA-3'; HPRT reverse, 5'-CAC AAT CAA GAC ATT CTT TCC AGT-3'. Thermal cycling conditions set in the 7500 Fast Real-Time PCR System (Applied Biosystems, USA) involved an initial denaturation step (10 min, 95°C) followed by 40 cycles of denaturation (15 sec, 95°C), annealing (30 sec, 55°C), and extension (30 sec, 72°C).

Differential Gene Expression Profiling

Microarray based gene expression profiling and scanning, feature extraction and data normalization of microarrays were performed as described previously [25]. Complete data sets for the IL-4 regulated transcriptome in HCAEC are available in the NCBI GEO data repository, accession number GSE64860.

Microarray Data Analyses

The preprocessed microarray data was analyzed using GeneSpring GX 9.0 Software (Agilent Tech. Inc.) with default settings for two color arrays and a fold change (FC) cutoff of 2. Using MetaCore™ GeneGO software (Thomson Reuters, <http://portal.genego.com>), genes regulated ≥ 2 fold in their expression and satisfying a *P* value < 0.05 were grouped into pathways according to their biologic functions and gene ontology (GO) classes.

Immunofluorescence Staining

HCAEC were grown in four-chamber culture slides coated with rat tail collagen type I (diluted 0.01% in sterile pyrogen-free water; BD Biosciences, USA). To stain for VE-cadherin, HCAEC were grown to a confluent monolayer. After treatment with appropriate stimuli, cells were fixed with 4% formalin in PBS for 20 min. After washing three times with PBS (pH 7.4) at room temperature (RT), slides were treated with blocking solution for 1 h at RT.

Depending on the source of secondary antibodies, blocking solution containing either 10% goat serum and 1% BSA (for secondary antibodies derived from goat) or 10% rabbit serum and 1% BSA in PBS (for secondary antibodies derived from rabbit) was used. After washing three times with PBS at RT, slides were incubated with primary antibodies diluted in blocking solution at 4°C overnight. The following antibodies were used with dilutions indicated: rabbit anti-VE-cadherin, polyclonal (1:100; Product No. 2158, Cell Signaling Technology), rabbit anti-phospho LIMK2, polyclonal (1:300; Product No. Ab131343, Abcam), rabbit anti-phospho CFL, polyclonal (1:500; Product No. Ab100836, Abcam), goat anti-Wnt5A, polyclonal (1:500; Cat. No. AF645, R&D Systems). Slides were then washed three times with PBS at RT.

Depending on the first antibody's species, slides were incubated with Alexa 568 labelled goat anti-rabbit or rabbit anti-goat secondary antibodies (1:2000; Molecular Probes, Invitrogen, USA) for 1 h at RT in the dark. Incubations with secondary antibody were combined with Alexa Fluor 488 Phalloidin (1:80; Molecular Probes, Invitrogen, USA) to visualize F-actin. Slides were washed three times with PBS at RT, counterstained with 10 µg/mL diamidino-phenylindole (DAPI; Sigma-Aldrich) and mounted using ProLong® Gold Antifade (Life Technologies, USA). Images were captured using an Axioscope microscope equipped with an AxioCam MRm digital camera and the associated AxioVision Rel.4.6 software (Carl Zeiss, Feldbach Switzerland). Fluorescent intensity was quantified from five different areas of the

respective fluorescent images using ImageJ based Fiji software (Fiji is just ImageJ) and corrected for background fluorescence to obtain cellular fluorescent intensity.

Inhibition of Rho associated protein serine/threonine kinases (ROCK)

Y-27632 (Calbiochem; Millipore, USA) at a concentration of 10 μ M [26] was used to inhibit the activation of ROCK. ROCK inhibition experiments were performed by incubating cells in medium containing Y-27632 alone or in combination with IL-4 for 1 h and 4 h.

Live Cell Imaging of Actin

HCAEC monolayers were grown in rat tail collagen type I coated optical 96 microwell culture plates (Thermo Scientific, USA). Cells were incubated with CellLight® Actin-RFP probe (Cat. No. C10583, Life Technologies, USA) according to manufacturer's instructions. After medium change, cells were treated with IL-4 or Wnt5A alone or in combination with sFRP1 or WIF1. Cells were further incubated up to 12 h. Images of live actin cytoskeleton organization were obtained using the Axio Observer.Z1 inverted microscope equipped with an AxioCam MRm digital camera and the associated ZEN 2012 software (Carl Zeiss, Feldbach, Switzerland).

Wnt5A Silencing

To knockdown Wnt5A expression, HCAEC grown up to 80% confluency in 24-well plates were incubated with transfection complexes formed from Wnt5A-siRNA (5 nM; Hs_Wnt5A_6, Cat. No. SI03025596; Qiagen) and 6 μ L/mL HiPerFect Transfection reagent (Qiagen GmbH, Hilden, Germany) in EBM-2 basal medium (Clonetics, Lonza, USA) for 24 h. After splitting using Trypsin EDTA, transfected cells were seeded onto collagen coated 6 well plates, retransfected for an additional round as above and incubated until the cells reached 90% confluency. HCAEC were also transfected with validated AllStars negative control siRNA (Qiagen) in parallel to control for 'off target' effects of siRNAs. Cells were then either treated with IL-4 for 8 h and lysed (for qRT-PCR analyses) or trypsinized and seeded into collagen-coated 8W10E+ arrays (for ECIS barrier function assays, see below). Treatments were carried out in EGM-2 MV medium with 2% FBS devoid of transfection complexes. To immunostain for Wnt5A, HCAEC transfected once with Wnt5A-siRNA were harvested by trypsinization and seeded into collagen-coated BD Falcon 4 chamber culture slides (BD Biosciences, USA). There, an additional round of Wnt5A-siRNA transfection was performed as in 24-well plates, incubated until the cells attained monolayer confluency and fixed for immunostaining.

Electric Cell-substrate Impedance Sensing (ECIS) of Endothelial Barrier Function

Using ECIS, the response of endothelial barrier to the stimulus can be assessed by continuously recording changes in transendothelial resistance (TEER) [27,28]. Endothelial barrier function was detected in real time using the ECIS® Z-theta system (Applied Biophysics) with associated software v.1.2.126 PC as follows: after equilibrating with EBM-2 basal medium (Clonetics, Lonza, USA) for 24 h, 8W10E+ arrays were coated with rat tail collagen type I (diluted 0.01% in sterile pyrogen-free water; BD Biosciences, USA) for 12 h. A monodisperse suspension of HCAEC in EGM-2 MV medium (Clonetics, Lonza, USA) supplemented with 5% FBS was added to the arrays at a density of 80,000–90,000 cells/well and incubated up to 24 h to form a uniform dense monolayer (S1 Fig.). Treatments were carried out in fresh medium with or without stimuli. Resistance of HCAEC monolayer was measured in Ohms at multiple frequencies ranging from 62.6 Hz to 64 kHz. Each of the eight wells of the 8W10E+ arrays contain 40 electrodes that trace the cells at 40 different locations in each well. The measurements from each well were averaged.

Automated Cell Migration Assay Using ECIS

The non-invasive ECIS assisted wound healing assay makes a highly reproducible wound with a specific diameter of 250 μm without damaging cells in the surrounding region in 8W1E arrays [29]. It was used for studying cell migration and was performed as follows: equilibration and collagen coating of 8W1E single electrode arrays were performed as described above for 8W10E+ arrays. A monodisperse suspension of HCAEC in EGM-2 MV medium (Clonetics, Lonza, USA) supplemented with 5% FBS was added to the arrays at a density of 80,000–90,000 cells/well and incubated up to 24 h to form a uniform dense monolayer. Treatments were carried out as described above for barrier function assays. Three hours after treatment, wounding was activated with default conditions for 8W1E arrays (1400 μA , 60000 Hz for 20 sec). This killed the treated cells adhering to the electrode surface in 8W1E slides to create a wound. Thereafter, impedance was continuously recorded to observe the migration of cells to the wounded area to form a confluent HCAEC monolayer.

Statistical Analysis

Data were analyzed using GraphPad Prism software version 5.04 (GraphPad Software, San Diego, CA). An unpaired 2-tailed Student's *t*-test was used and differences were considered statistically significant at $P < 0.05$.

Results

Gene expression changes in IL-4 treated adult human VEC

To identify all genes regulated by IL-4 treatment in HCAEC, we performed dual channel oligonucleotide based transcriptome profiling. The transcriptome profile of HCAEC treated with IL-4 for 8 h was compared to that of non-treated cells using whole human genome oligomicroarrays. The preprocessed gene expression data was analyzed by GeneSpring software to identify the genes in treated cells that showed a minimum two fold change in expression compared with non-treated cells. IL-4 regulated 2747 genes, of which 1395 genes were upregulated and 1352 genes were down regulated. *PMCH*, *HAS3*, *CCL26*, *OTOGL*, *TMTC1*, *CH25H*, *VCAM1*, *DKK2*, *SLC10A7*, *MASP1*, *COL3A1* and *WNT5A* were the genes most upregulated by IL-4. The top one hundred genes upregulated by IL-4 in HCAEC are listed in S1 Table. *LRRC14B*, *DNAH2*, *TMEM191B*, *FAM47B*, *GPR116*, *TTC9*, *NOG*, *OR13C8*, *GPRC6A*, *CSN3*, *TMEM236* and *PRKG2* were the genes most downregulated by IL-4. The top one hundred genes downregulated by IL-4 in HCAEC are listed in S2 Table.

All differentially regulated genes contained in the preprocessed microarray data were subjected to GO analyses using MetaCore™ GeneGO software. Using this tool, genes regulated at least two fold in their expression were clustered on the basis of their function to generate statistically significant cellular pathways. Among the top twenty five biological pathways regulated by IL-4, six were associated with immune responses (Figs. 1A and 1B). The 'Immune response_Oncostatin M signaling via JAK-Stat in human cells' is the pathway most significantly regulated by IL-4 treatment in HCAEC (Fig. 1A). Genes of this pathway regulated by IL-4 (e.g. *CCL2*, *IL6ST*, *MMP1* and *VEGFA*; Table 1) are mainly associated with immune responses involving monocyte-endothelial interactions and endothelial permeabilization. The 'Development_Regulation of epithelial-to-mesenchymal transition (EMT)' is the second most significant biological process for IL-4 in HCAEC (Fig. 1A). Among the genes of this pathway regulated by IL-4 (Table 1), *DLL4* and *PDGFB* are involved in cell proliferation and migration, *SNAI1* and *ZEB1* are involved in promoting the transition of cells from epithelial to mesenchymal state, *SNAI2* is involved in repressing the expression of cellular junctional proteins and *Wnt5A* is involved in cell migration and inflammation.

The 'Cytoskeleton remodeling_TGF, Wnt and cytoskeletal remodeling' pathway is the third most significant biological process for IL-4 in HCAEC (Fig. 1A). Among the genes regulated in this pathway are *Wnt5A*, *Wnt1*, *VEGFA*, *LIMK2* and *CFL1* (Table 1). The MetaCore™ map of this pathway showing these genes within their signaling context indicates that IL-4 upregulates Wnt as most significant ligand for the cytoskeleton remodeling (Fig. 2, upper right quarter), and causes downstream regulation of LIMK2 and CFL1 (Fig. 2, lower left quarter). *LIMK2* and *CFL1* are responsible for actin polymerization. Among the other genes

of this pathway are *KDR* and *FZDs* (Fig. 2, Table 1), which are involved in VEGF and Wnt signaling.

Data from our study confirm previous findings that IL-4 upregulates VCAM-1 [10-12], IL-6 [12-14], MCP [12,14] and LIFR [12] in VEC (S1 Table). Thus, it corroborates the proposed role of IL-4 as an 'alternative inflammatory' cytokine. With respect to transcription factors mediating IL-4 induced gene expression in VEC, the present study demonstrates that IL-4 upregulates the expression of genes encoding FOSB (a member of the activator protein-1 family), GATA3 and EGR1 (S3 Table).

Confirmation of Wnt5A expression by qRT-PCR and immunofluorescence staining

Since Wnt5A was previously identified as an inflammatory mediator, and expression of the gene is shown to be significantly upregulated by IL-4 in microarray analysis, we measured Wnt5A mRNA levels in HCAEC treated with IL-4 for 8 h using qRT-PCR. Consistent with the microarray data, IL-4 significantly upregulated Wnt5A mRNA levels (Fig. 3A). The induction of IL-6 mRNA was considered as indication of positive IL-4 stimulation of HCAEC (Fig. 3B). To confirm that IL-4 induced Wnt5A expression is not only specific for HCAEC but also for endothelial cells from different vascular beds, we measured Wnt5A mRNA level in IL-4 treated HPAEC. Consistent with findings obtained in HCAEC, 8 h treatment with IL-4 significantly upregulated Wnt5A in HPAEC (Fig. 3A). We further confirmed Wnt5A induction at the protein level by immunofluorescence staining. In accordance with qRT-PCR and microarray data, treatment with IL-4 notably increased the levels of Wnt5A protein in HCAEC (Fig. 3C).

LIM kinase (LIMK) 2 and Cofilin-1 (CFL1) are phosphorylated in IL-4 treated HCAEC

GO analysis of gene expression data shows that IL-4 regulated the *LIMK2* and *CFL1* genes, which are involved in cytoskeleton remodeling (Fig. 2, Table 1). LIMK2, a serine/threonine/tyrosine kinase, is a downstream target of ROCK. When phosphorylated by the activated ROCK, LIMK2 phosphorylates the actin depolymerization factor CFL1 [30-32]. Therefore, we investigated whether LIMK2 and CFL1 proteins are phosphorylated following IL-4 treatment in HCAEC. Immunofluorescence staining employing specific antibodies were used to detect the phosphorylated forms of LIMK2 (pLIMK2) and CFL1 (pCFL1). Compared to non-treated cells, pLIMK2 (Fig. 4, upper panel) and pCFL1 (Fig. 4, lower panel) levels were markedly increased in HCAEC treated with IL-4 for 1 h and 4 h respectively. Combining IL-4 with the ROCK inhibitor Y-27632 notably suppressed the phosphorylation of LIMK2 (Figs. 4A and 4B) and CFL1 (Figs. 4A and 4B) in HCAEC.

IL-4 induced stress fiber formation can be decreased by Wnt antagonist

Since inactivation of CFL1 by phosphorylation prevents actin depolymerization resulting in F-actin stress fiber formation [31-33], and IL-4 treatment induced its phosphorylation, we next investigated whether IL-4 causes stress fiber formation. Alterations in actin organization and stress fiber formation were visualized by imaging actin-RFP in IL-4 treated live HCAEC. Actin-RFP showed only a few thin stress fibers in non-treated HCAEC whereas formation of thick actin stress fibers were visible in IL-4 treated cells (Fig. 5).

Functional clustering of the IL-4 regulated transcriptome showed upregulation of Wnt5A, and this occurs upstream of LIMK2 and CFL1 regulation in the cytoskeleton remodeling process (Fig. 2). Having verified upregulated Wnt5A expression and increased stress fiber formation through LIMK2 and CFL1 phosphorylation in IL-4 treated HCAEC, we next investigated the role of Wnt5A in IL-4 induced stress fiber formation using Wnt antagonists. As Frizzleds (Fzds) have long been considered the receptors for Wnts, and transcriptome profiling in this study showed upregulation of some *Fzd* genes by IL-4 in HCAEC, we first attempted to block Wnt5A/Fzd signaling using sFRP1. Treating HCAEC with IL-4 in the presence of sFRP1 did not influence actin stress fiber formation (Fig. 5). As Ryk is described as an alternative receptor for Wnts [34], we next tested whether inhibiting Wnt5A/Ryk interaction by using WIF1 has an effect on IL-4 induced stress fiber formation. Stress fiber formation was notably suppressed when HCAEC were treated with a combination of IL-4 and WIF1 (Fig. 5). HCAEC showed increased stress fiber formation upon Wnt5A treatment, however this was notably suppressed after treatment with a combination of Wnt5A and WIF1 (Fig. 5).

IL-4 disrupts the assembly of VE-cadherin in inter-endothelial junctions (IEJs)

Actin stress fiber formation leads to disassembly of VE-cadherin in IEJs and causes intercellular gap formation in endothelial monolayers [35]. Since IL-4 induced stress fiber formation, we next investigated if IL-4 affected VE-cadherin assembly in HCAEC. Immunofluorescence staining showed continuous distribution of VE-cadherin along the cellular periphery, and tight intercellular contacts in non-treated HCAEC monolayers (Fig. 6A). In contrast, IL-4 treated HCAEC monolayers showed small inter-endothelial gaps with marked loss of VE-cadherin at intercellular regions (Fig. 6B).

IL-4 induced endothelial hyperpermeability is decreased by silencing Wnt5A

Stress fiber formation and IEJ disruption accompanied by inter-endothelial gap formation impairs barrier function and increases permeability of endothelial monolayers [35]. Since IL-4 upregulated Wnt5A, and inhibiting Wnt5A with WIF1 decreased IL-4 induced stress fiber formation in HCAEC, we investigated whether Wnt5A mediated IL-4 induced endothelial hyperpermeability. Alterations in TEER of tight HCAEC monolayers cultured in 8W10E+

slides were recorded in real time by ECIS. Treatment with IL-4 significantly reduced the TEER of HCAEC monolayers to alternating current (AC). Notably, IL-4 induced alterations in TEER became apparent 3 h after treatment with IL-4 and persisted for more than 8 h (Fig. 7A).

Next, we tested whether silencing Wnt5A improves the barrier function of IL-4 treated HCAEC monolayers. HCAEC were transfected with siRNA against Wnt5A. qRT-PCR showed that Wnt5A mRNA expression was approximately 60% lower in Wnt5A-siRNA transfected cells than in cells transfected with negative control siRNA (S2A Fig.). Accordingly, immunofluorescence staining showed decreased Wnt5A protein expression in Wnt5A-siRNA transfected HCAEC compared with negative control siRNA transfected cells (S2B and S2C Figs.).

Upon IL-4 treatment, Wnt5A silenced HCAEC showed significantly increased TEER compared with non-transfected HCAEC (Fig. 7A). In HCAEC transfected with negative control siRNA, the response to IL-4 was not altered (Fig. 7B).

Since IL-4 upregulated IL-6 in HCAEC in the present study (Fig. 3B), and IL-6 has been reported to increase permeability of HUVEC [36] and bovine vascular endothelial cells (BVEC) [37], we also investigated whether IL-6 increased permeability of HCAEC monolayers. Treatment with IL-6 did not alter the TEER of HCAEC monolayer to AC, thereby indicating that IL-6 does not influence the permeability characteristics of HCAEC (Fig. 7C).

IL-4 impairs migration of HCAEC, which can be restored by ROCK inhibition

Since IL-4 increased the formation of actin stress fibers and caused inter-endothelial gap formation, we investigated whether IL-4 would also affect the motility of HCAEC. In an ECIS supported wound healing and cell migration assay, IL-4 treated HCAEC exhibited a lower impedance and required a longer time to heal the wound compared with non-treated cells (Fig. 8A). This indicates that IL-4 significantly reduces endothelial cell motility, causing delayed wound closure.

The present study shows that IL-4 induced phosphorylation of LIMK2 and CFL1 can be decreased by inhibiting ROCK. Since ROCK regulates cytoskeleton remodeling, cell–cell adhesion and cell motility [32], we investigated whether inhibiting ROCK prevents IL-4 induced impairment of HCAEC motility. Cells treated with a combination of IL-4 and the ROCK inhibitor Y-27632 showed significantly higher motility rates and faster wound closure than cells treated with only IL-4 (Fig. 8B).

IL-4 upregulates Wnt5A expression in human macrophages

Since macrophages also play a pivotal role in Th2 inflammation, we asked whether Wnt5A expression is also upregulated in IL-4 activated human M2 type macrophages. Treatment with IL-4 significantly upregulated Wnt5A mRNA expression in macrophages (Fig. 9).

Discussion

VEC play an important role in maintaining vascular homeostasis. During inflammation, soluble mediators secreted by activated immune cells paracrinically act on VEC and significantly alter their functions to confer 'inflamed' or 'activated' phenotypes on them. IL-4 is a potent Th2 cytokine known to cause activation of VEC and induce endothelial barrier dysfunction [21]. However, the exact mechanisms responsible for IL-4 dependent endothelial dysfunction in VEC remained unclear. In the present study, we detected all genes regulated by paracrine IL-4 signaling in adult VEC by whole human genome microarray based transcriptome profiling (Fig. 1, S1 and S2 Tables).

This is the first study to demonstrate that IL-4 significantly upregulates Wnt5A expression in adult VEC. A previous study demonstrated that HUVEC treated with a combination of TNF- α , IL-1 and IL-8 upregulated the expression of Wnt5A mRNA [38]. Wnt5A is a non-canonical Wnt ligand, recently identified as a pro-inflammatory mediator of macrophage activation in vascular inflammation [24]. Wnt5A has been demonstrated to enhance the permeability of HUVEC monolayers in a ^{14}C sucrose permeability test [39] and IL-4 caused morphological changes and induced inter-endothelial gap formation in HUVEC [17]. Furthermore IL-4 has been demonstrated to induce hyperpermeability of HUVEC [21]. Inter-endothelial gap formation caused by cytoskeletal rearrangements impairs the barrier functions of endothelial monolayers and is the principal pathway causing endothelial hyperpermeability and subsequent edema formation in inflammation [40]. Endothelial hyperpermeability accounts for increased efflux of plasma through microvessel walls into neighboring tissues, leading to the formation of protein rich tissue edema. Edema formation resulting from vascular leakage is an important consequence of allergic inflammation [21] and a most common side effect of IL-4 therapy in human cancer patients [41]. Addressing a potential role for Wnt5A in IL-4 induced endothelial cytoskeleton remodeling, GO analyses for the current study point to Wnt5A as a potential ligand for the 'Cytoskeleton remodeling_TGF, Wnt and cytoskeletal remodeling' pathway (Fig. 2). A prominent role for Wnt5A in mediating IL-4 induced cytoskeleton remodeling is evident from our observation that IL-4 induced actin stress fiber formation can be prevented by blocking Wnt5A signaling (Fig. 5). Further proof for the involvement of Wnt5A is provided by functional experiments demonstrating that the enhanced permeability of HCAEC monolayers upon IL-4 treatment can be significantly decreased by silencing Wnt5A expression (Fig. 7A). Our findings support the crucial role of

Wnt5A in stress fiber formation and inter-endothelial gap formation, leading to impaired barrier function in IL-4 treated HCAEC.

Wnt5A signals mainly through Fzd receptors but can also function through Ryk, a member of the family of atypical receptor tyrosine-protein kinases (RTKs). Ryk consists of an extracellular Wnt-binding domain, a PDZ binding motif and an intracellular inactive tyrosine kinase domain. Its Wnt-binding domain is homologous to the extracellular Wnt antagonist, WIF protein. sFRP1 is another Wnt antagonist that contains a frizzled like cysteine-rich domain (CRD) homologous to the extracellular Wnt-binding domains of Fzd receptors [34]. The availability of the receptor, presence of Wnt antagonists and the cellular environment determines which receptors Wnts engages and the signals that are generated. The involvement of Ryk, but not Fzd receptors, in IL-4 induced Wnt5A signaling in HCAECs is obvious from our observation that stress fiber formation was prevented in the presence of WIF1 but not sFRP1 (Fig. 5). Others have demonstrated that Wnt5A/Ryk signaling through Rho-kinase activation inhibits axon growth in rats [42]. We propose that in HCAEC, Wnt5A signaling through Ryk receptor activates ROCK that in turn phosphorylates LIMK2. Activated pLIMK2 in turn phosphorylates CFL1 that is then deactivated, and as a consequence, allows actin fiber polymerization. This disrupts VE-cadherin assembly in IEJs leading to the formation of inter-endothelial gaps, as we have observed in the present study (Fig. 6B). The involvement of ROCK as a downstream effector of Wnt5A/Ryk signaling in HCAEC is very well supported by the observations that phosphorylation of LIMK2 and CFL1 following IL-4 treatment can be decreased by inhibiting ROCK (Fig. 4). The function of ROCK in IL-4 induced cytoskeleton remodeling is further evident from the standardized ECIS cell migration assay that shows improved migratory and wound healing capacity of cells treated with a combination of IL-4 and ROCK inhibitor (Figs. 8A and 8B).

Intriguingly, the present study confirms that IL-6 is upregulated by IL-4 in HCAEC but IL-6 does not influence TEER in the ECIS based standardized permeability assay (Fig. 7C), even though it increases permeability in HUVEC [36] and BVEC [37]. Further studies are warranted to confirm that IL-6 is not responsible for increased VEC permeability, or whether this effect of IL-6 varies between endothelial cells from different vascular beds and thus depends on endothelial heterogeneity.

The whole genome transcriptome analysis of IL-4 treated HCAEC further revealed induction of vascular endothelial growth factor (VEGF)-A (Table 1, Fig. 2). A previous study showed that IL-4 increased the production of VEGF in unstimulated synovial fibroblasts [43]. VEGF-A acts as a proangiogenic factor in wound healing. It enhances endothelial cell migration from pre-existing blood vessels and promotes the recruitment of endothelial progenitor cells (EPCs) from peripheral circulation [44]. Surprisingly, the present study demonstrates an inhibitory effect of IL-4 on endothelial cell migration while upregulating VEGF-A. Even though

this contradicts the effects of VEGF in stimulating endothelial cell migration, it could be explained by the observation that IL-4 downregulates expression of VEGFR-2 (Table 1, Fig. 2). VEGFR-2 (also known as KDR) is a receptor specific for VEGF [44] and downregulation would block autocrine VEGF-A signaling in endothelial cells. This is a likely feedback mechanism inhibiting angiogenesis. As soluble factors secreted by VEC paracrinically act on other immune cells such as macrophages, it is also possible that VEGF-A produced by VEC interacts with VEGF receptors expressed on other immune cells. This view is well supported by previous studies which demonstrated that VEGF-A acted as a chemoattractant for monocytes expressing VEGF receptor 1 [45-48].

Among the genes highly expressed upon IL-4 treatment of HCAEC (S1 Table), pro-melanin-concentrating hormone (PMCH) has also been described previously as highly induced by activated Th2 cells [49]. IL-4 triggered expression of hyaluronan synthase 3 (HAS3) may facilitate the adhesion and migration of activated immune cells and cancer cells during inflammatory response and cancer metastasis, respectively. Induction of CCL26 by IL-4 has already been described in VEC and it acts as a chemokine for eosinophils [50].

Conclusions

Our study indicates that Wnt5A is crucially involved in cytoskeleton rearrangement mediated by IL-4 in VEC. We further show that Wnt5A signals downstream through the ROCK–LIMK2–CFL1 pathway and show that Ryk is a possible receptor for Wnt5A signaling in VEC. Here we demonstrate a crucial role for Wnt5A in IL-4 induced actin cytoskeleton remodeling and consequent barrier dysfunction and hyperpermeability of VEC. Therapeutic approaches targeting Wnt5A may reduce microvascular leakage and subsequent edema formation associated with IL-4 driven pathophysiological conditions such as allergic inflammation, tumor inflammation, and angioedema. Moreover, we show for the first time that IL-4 induces Wnt5A in human M2 type macrophages, which is different to the Toll-like receptor (TLR) mediated Wnt5A induction described previously [24]. Together, this establishes Wnt5A as a component of both classically and alternatively activated macrophages. Further studies delineating the specific role of Wnt5A in alternatively activated macrophages would provide novel insights into the inflammatory responses in diseases associated with Th2 activity.

Table 1. Key genes regulated by IL-4 in ‘Immune response_Oncostatin M signaling via JAK-Stat in human cells’, ‘Development_Regulation of epithelial-to-mesenchymal transition (EMT)’ and ‘Cytoskeleton remodeling_TGF, Wnt and cytoskeletal remodeling’ pathways in HCAEC.

Gene Symbol	Accession	Sequence Description	Regulation
CAV1 ^c	NM_001172895	Homo sapiens caveolin 1	Down
CCL2 ^a	NM_002982	Homo sapiens chemokine (C-C motif) ligand 2	Up
CFL1 ^c	NM_005507	Homo sapiens cofilin 1	Down
CCND1 ^{a,c}	NM_053056	Homo sapiens cyclin D1	Down
DLL4 ^b	NM_019074	Homo sapiens delta-like 4	Down
FZD4 ^{b,c}	NM_012193	Homo sapiens frizzled class receptor 4	Up
FZD8 ^{b,c}	NM_031866	Homo sapiens frizzled class receptor 8	Up
FOXO3 ^c	NM_001455	Homo sapiens forkhead box O3	Up
HEY1 ^b	NM_001040708	Homo sapiens hes-related family bHLH transcription factor with YRPW motif 1	Down
IL6ST ^a	NM_001190981	Homo sapiens interleukin 6 signal transducer	Up
JAG1 ^b	NM_000214	Homo sapiens jagged 1	Up
KDR ^c	NM_002253	Homo sapiens kinase insert domain receptor	Down
LIFR ^a	NM_002310	Homo sapiens leukemia inhibitory factor receptor alpha	Up
LIMK2 ^c	NM_001031801	Homo sapiens LIM domain kinase 2	Down
MAPK13 ^c	NM_002754	Homo sapiens mitogen-activated protein kinase 13	Down
MAP2K3 ^c	NM_002756	Homo sapiens mitogen-activated protein kinase kinase 3	Down
MMP1 ^a	NM_002421	Homo sapiens matrix metalloproteinase 1	Up
MMP7 ^c	NM_002423	Homo sapiens matrix metalloproteinase 7	Up
MYLK ^c	NM_053025	Homo sapiens myosin light chain kinase	Down
MYLK2 ^c	NM_033118	Homo sapiens myosin light chain kinase 2	Down
PDGFβ ^b	NM_002608	Homo sapiens platelet-derived growth factor beta polypeptide	Down
SNAI1 ^b	NM_005985	Homo sapiens snail homolog 1	Down
SNAI2 ^b	NM_003068	Homo sapiens snail homolog 2	Down
TGFβ2 ^b	NM_003238	Homo sapiens transforming growth factor, beta 2	Up
TGFβ3 ^b	NM_003239	Homo sapiens transforming growth factor, beta 3	Up
VEGFA ^{a,c}	NM_001025366	Homo sapiens vascular endothelial growth factor A	Up
WNT5A ^{b,c}	NM_003392	Homo sapiens wingless-type MMTV integration site family, member 5A	Up
ZEB1 ^b	NM_001128128	Homo sapiens zinc finger E-box binding homeobox 1	Down

^aGenes regulated by IL-4 in ‘Immune response_Oncostatin M signaling via JAK-Stat in human cells’ pathway.

^bGenes regulated by IL-4 in ‘Development_Regulation of epithelial-to-mesenchymal transition (EMT)’ pathway.

^cGenes regulated by IL-4 in ‘Cytoskeleton remodeling_TGF, Wnt and cytoskeletal remodeling’ pathway.

Figure 1

A

B

Fig. 1. The twenty five biological pathways most significantly ($P < 0.05$) regulated by IL-4 treatment in HCAEC. (A, B) Pathways represented as histograms are ranked by the $-\log$ value (P value). Length of histogram corresponds to the number of genes associated with that specific pathway.

Figure 2

Fig. 2. Metacore™ map showing the signaling context of the genes contained in the 'Cytoskeleton remodeling_TGF, Wnt and cytoskeletal remodeling' pathway. Genes regulated by IL-4 are marked by red and blue thermometer icons representing upregulated and downregulated gene expression respectively.

Figure 3

Fig. 3. Expression of Wnt5A in IL-4 treated HCAEC. Fold changes in the expression of (A) Wnt5A mRNA in 8 h IL-4 treated HCAEC and HPAEC and (B) IL-6 mRNA in 8 h IL-4 treated HCAEC. Data were obtained from three independent qRT-PCR experiments run with duplicate samples and expressed as the mean \pm SEM. * P <0.05, ** P <0.005 using an unpaired Student's t -test. (C) Wnt5A protein expression in non-treated and IL-4 treated HCAEC. Wnt5A is immunostained (red). Zeiss Axioskope, magnification 20 \times .

Figure 4

A

B

Fig. 4. Phosphorylation of LIMK2 and CFL1 in IL-4 treated HCAEC. (A) pLIMK2 and pCofilin-1 were immunostained (red) in HCAEC treated with IL-4 either alone or in combination with Y-27632. F-actin (fluorescent phalloidin, green) and nuclei (DAPI, blue) were also stained. Zeiss Axioscope, magnification 20x. (B) Mean cellular fluorescent intensities of pLIMK2 and pCFL1 quantified by Fiji software.

Figure 5

Fig. 5. Stress fiber formation in IL-4 treated HCAEC. Live actin-RFP staining showing the formation of actin stress fibers in HCAEC treated with IL-4 or Wnt5A in the absence or presence of sFRP1 and WIF1. Zeiss Axio Observer.Z1, magnification 40x.

Figure 6

Fig. 6. Assembly of VE-cadherin in IL-4 treated HCAEC. VE-cadherin immunostained (red) in HCAEC either non-treated (A) or treated with IL- 4 for 8 h (B). Nuclei (DAPI, blue). Zeiss Axioskope, magnification 40 \times .

Figure 7

A

B

C

Fig. 7. ECIS barrier function assays showing the effect of Wnt5A in IL-4 induced hyperpermeability of HCAEC. Uniform confluent monolayers of HCAEC cultured in stabilized and collagen coated ECIS 8W10E+ arrays were treated with IL-4. TEER of HCAEC monolayers was measured in Ohms continuously at multiple frequencies ranging from 62.6 Hz to 64 kHz, normalized to its value at time zero and plotted with respect to time. Stimulations conducted in duplicate wells were grouped and averaged to plot a single curve with error bars representing SD. Figures shown depict the resistance measurements conducted at 4000 Hz and represent four independent experiments. (A) 1, non-treated Wnt5A-siRNA transfected HCAEC; 2, non-treated non-transfected HCAEC; 3, IL-4 treated Wnt5A-siRNA transfected HCAEC; 4, IL-4 treated non-transfected HCAEC. (B) 1, non-treated negative control siRNA transfected HCAEC; 2, IL-4 treated negative control siRNA transfected HCAEC; 3, IL-4 treated non-transfected HCAEC. (C) Black, non-treated; green, IL-6.

Figure 8

Fig. 8. Automated wound healing assay showing decreased motility of IL-4 treated HCAEC. Uniform confluent monolayers of HCAEC cultured in stabilized and collagen coated ECIS 8W1E cultureware were treated with IL-4 either alone or in combination with Y-27632. Three hours after treatment, wells were subjected to an elevated electric field to create a wound. Measurements were started immediately after wounding. Impedance of HCAEC monolayer was measured in Ohms every 5 min at multiple frequencies ranging from 62.6 Hz to 64 kHz and plotted with respect to time. Representative figures depict the impedance of wells after wounding was applied. Figures shown depict the measurements conducted at 4000 Hz and represent four independent experiments. (A) Black, non-treated; Blue, IL-4. (B) Black, control with Y27632; Green, IL-4 + Y27632.

Figure 9

Fig. 9. Wnt5A expression in IL-4 activated human macrophages. Fold changes in the expression of Wnt5A mRNA in IL-4 treated human macrophages. Data were obtained from two independent qRT-PCR experiments run with duplicate samples using RNA isolated from macrophages from four different donors and expressed as the mean \pm SEM. * $P < 0.05$ using an unpaired Student's t -test.

SUPPLEMENTAL MATERIAL

SUPPLEMENTAL TABLES

S1 Table. The top 100 genes upregulated by IL-4 in HCAEC.

Gene symbol	Accession	Sequence description	Fold change
PMCH	NM_002674	Homo sapiens pro-melanin-concentrating hormone	41,795143
HAS3	NM_005329	Homo sapiens hyaluronan synthase 3	40,64191
CCL26	NM_006072	Homo sapiens chemokine (C-C motif) ligand 26	37,32348
OTOGL	NM_173591	Homo sapiens otogelin-like	28,089672
TMTC1	NM_175861	Homo sapiens transmembrane and tetratricopeptide repeat containing 1	26,668077
CH25H	NM_003956	Homo sapiens cholesterol 25-hydroxylase	21,65999
VCAM1	NM_001078	Homo sapiens vascular cell adhesion molecule 1	19,443674
DKK2	NM_014421	Homo sapiens dickkopf homolog 2	12,351812
SLC10A7	NM_032128	Homo sapiens solute carrier family 10 (sodium/bile acid cotransporter family), member 7	12,2331505
MASP1	NM_001031849	Homo sapiens mannan-binding lectin serine peptidase 1	11,580042
COL3A1	NM_000090	Homo sapiens collagen, type III, alpha 1	10,082533
WNT5A	NM_003392	Homo sapiens wntless-type MMTV integration site family, member 5A	9,96113
PKD1L1	NM_138295	Homo sapiens polycystic kidney disease 1 like 1	9,657538
SOCS1	NM_003745	Homo sapiens suppressor of cytokine signalling 1	9,610145
IGF1	NM_000618	Homo sapiens insulin-like growth factor 1	9,396036
ERAP1	NM_016442	Homo sapiens endoplasmic reticulum aminopeptidase 1	9,268832
PLCB4	NM_182797	Homo sapiens phospholipase C, beta 4	8,71052
HS3ST1	NM_005114	Homo sapiens heparan sulfate (glucosamine) 3-O-sulfotransferase 1	8,354389
FILIP1L	NM_182909	Homo sapiens filamin A interacting protein 1-like	8,258449
NCF2	NM_000433	Homo sapiens neutrophil cytosolic factor 2	8,030248
MAP3K8	NM_005204	Homo sapiens mitogen-activated protein kinase kinase kinase 8	7,8828645
BMP2	NM_001200	Homo sapiens bone morphogenetic protein 2	7,6503243
LIFR	NM_002310	Homo sapiens leukemia inhibitory factor receptor alpha	7,4233665
BATF3	NM_018664	Homo sapiens basic leucine zipper transcription factor, ATF-like 3	7,255049
FOXC1	NM_001453	Homo sapiens forkhead box C1	7,21699
CISH	NM_145071	Homo sapiens cytokine inducible SH2-	7,0423675

		containing protein	
EGR1	NM_001964	Homo sapiens early growth response 1	7,0303206
MMP7	NM_002423	Homo sapiens matrix metalloproteinase 7	6,91629
AGXT2L1	NM_031279	Homo sapiens alanine-glyoxylate aminotransferase 2-like 1	6,9126115
FAM115C	NM_173678	Homo sapiens family with sequence similarity 115, member C	6,896242

SUPPLEMENTAL FIGURES

S1 Fig.

S1 Fig. HCAEC monolayer formation in ECIS arrays. Immediately after seeding HCAEC into 8W10E+ arrays with a density of 80,000- 90,000 cells/well, resistance measurements (in Ohms) were started and are shown as normalized resistance (subsequent values were divided by initial values). Increase in resistance over time indicates an increase in the formation of intercellular contacts. The steady state of resistance represents a tight monolayer stage exhibiting stable barrier function. Each single curve represents the resistance measurements conducted in duplicate wells which were grouped and averaged. Error bars of curves represent SD. Figures shown depict the resistance measurements conducted at 4000 Hz.

S2 Fig.

S2 Fig. Wnt5A knockdown efficiency. (A) Expression levels of Wnt5A mRNA in HCAEC transfected with 5 nM negative (neg.) control siRNA and Wnt5A siRNA. Data were obtained from three independent qRT-PCR experiments run with duplicate samples and expressed as the mean \pm SEM. * $P < 0.005$ of Student's *t*-test. Representative immunofluorescence staining depicting Wnt5A protein expression (red) in negative control siRNA transfected (B) and Wnt5A siRNA transfected (C) HCAEC. Green: F-actin, Blue: nuclei. Zeiss Axioskope, Magnification 20 \times .

7. CONCLUSIONS

The present study describes a novel inflammatory Wnt5A signaling mechanism affecting monolayer integrity and barrier function in human vascular endothelial cells. This pathway acts independent of the presence other inflammatory mediators such as TNF, IL-1 or IL-6 as summarized in Figure 6.

Figure 6. The paracrine and autocrine action of macrophage-derived and IL-4-induced Wnt5A on human vascular endothelial cells. Tight intercellular contacts at AJ in resting endothelial cells (left side of figure) are disrupted upon Wnt5A/Ryk signaling to form inter-endothelial gaps (right side of figure). MA, macrophages; Ag, Antigen; TCR, T cell receptor; IL-4R, IL-4 receptor; IFNγR, Interferon-γ receptor; Th1, type 1 helper T cell.

Whole genome transcriptome profiling and GO analyses revealed that Wnt5A mainly regulated the process of cytoskeleton remodelling involving *LIMK-2* and *CFL-1* in HCAEC. Wnt5A-induced phosphorylation of LIMK-2 and CFL-1 through activation of ROCK increased actin stress fiber formation and disrupted AJ proteins in IEJ (Figure 6). We demonstrated that Wnt5A-induced cytoskeleton remodelling could also affect endothelial cell motility and impair endothelial barrier

function. By application of the Ryk-specific Wnt antagonist WIF-1, and by silencing Ryk expression, we proved Ryk as the Wnt5A receptor upstream to the ROCK/LIMK-2/CFL-1 pathway regulating actin cytoskeleton remodelling. We further identified Wnt5A/Ryk signaling as the effector mechanism responsible for cytoskeleton remodelling and increased permeability in IL-4-treated HCAEC (Figure 6). Data obtained in these studies indicate a critical role for Wnt5A in mediating endothelial permeability in severe systemic inflammatory diseases like sepsis/septic shock, and in IL-4 driven allergic inflammation.

In conclusion, Wnt5A/Ryk signaling is a novel pro-inflammatory mechanism inducing barrier dysfunction in the vascular endothelium. The present study advances the current knowledge of systemic inflammation and opens new perspectives for therapeutic intervention in patients with severe systemic inflammatory diseases.

Further investigations are needed to unravel the intriguing finding of Wnt5A being induced by two different pathways that are evolutionary highly conserved, TLR-dependent and IL-4 dependent signaling.

8. ACKNOWLEDGMENTS

I would first like to thank God for giving me this PhD project through Prof. Schoedon and the knowledge, guidance and strength to successfully complete my doctoral studies.

I am grateful to Prof. Schoedon for the excellent mentoring she has provided throughout the study that has advanced my scientific knowledge and skills. I thank her for interesting discussions and the kindness and support shown to me.

I would like to thank Dr. Mårten Schneider for sharing his knowledge in flow cytometry and Dr. Christian Schaer for his valuable suggestions on microarray technique.

I gratefully acknowledge Prof. Christoph Renner and Prof. Christian Münz for serving as my thesis committee members.

A word of thanks goes to Dr. Julia Burgener, Dr. Esther Bächli and all members of Inflammation Research Unit at Division of Internal Medicine, USZ.

I am indebted to my parents and wife for love, support and understanding.

9. CURRICULUM VITAE

Surname: SKARIA
First Name: Tom
Date of Birth: 28.05.1984
Nationality: Indian

Education

2000-2002 Higher Secondary Examination (Science), Government of Kerala, India.
2002-2005 B.Sc. Biotechnology, Mahatma Gandhi University, Kottayam, Kerala, India.
2005-2007 M.Sc. Biotechnology, Bangalore University, India.
2009-2010 M.Sc. Molecular Biology, University of Skövde, Sweden.
 Title of Master thesis: "Alterations of complexes of oxidative phosphorylation in gastric carcinoma".
2010-2015 PhD Dissertation at the Inflammation Research Unit, Division of Internal Medicine, University Hospital of Zurich, University of Zurich. "Mechanisms of Inflammation in Response to Wnt5A and IL-4 in Human Vascular Endothelial Cells" under the supervision of Prof. Gabriele Schoedon, Prof. Christoph Renner and Prof. Christian Münz.
